THE RÔLE OF INSTINCT, EMOTION AND PERSONALITY IN DISORDERS OF THE HEART

WITH SUGGESTIONS FOR A CLINICAL RECORD*

C. MACFIE CAMPBELL, M.D.
BALTIMORE

In internal medicine, intensive study is devoted to the individual organ or system; it is frequently necessary to pay attention to the way in which the organs are linked together by the central nervous system or by the glands regulating the biochemistry of the body, but no higher integration is attempted. The actual individual is seldom reconstructed for the purposes of the internist; personality is a category that he does not use. So far as the study of personal factors is omitted, the study of the functions of the individual organs is incomplete. Not only does each organ have its definite routine task in relation to the domestic economy; it is also liable at any time to be commandeered for foreign service, when the individual has to react to an external situation of biologic importance. The individual reacts to such a situation in virtue of his innate instinctive equipment, and each instinctive reaction makes its special demand on the various organs. What from the outside is an instinctive reaction may on the inside apppear as an emotional experience; the instinctive flight or hiding from danger is at the same time registered as the emotion of fear. One instinct may conflict with another instinct; one instinctive reaction may be inhibited by another, or by factors more complex than instinct, for not all behavior is instinctive. Tradition or training may check the instinctive tendency to flight.

That part of the instinctive reaction which is inhibited or modified by other processes associated with memories, purpose, ideals, etc., may not manifest itself, but these movements are only the more obvious expression of the instinctive reaction; simultaneously with the movements of flight, actual or inhibited, the whole system is mobilized in the interests of the safety of the individual. Cannon has published interesting detailed studies on the physiology of this mobilization. We may check our tendency to flee, but against our wishes our heart beats wildly, our respiration is modified, our tongue cleaves to the roof of our mouth, our knees knock together and barely support us, and we break out into a cold sweat.

The action of the heart in such a critical situation cannot be understood under the simple categories of internal medicine; the internist is thus confronted with the problems of the instincts and the emotions. This is no unique situation in internal medicine; chorea, exophthalmic goiter and diabetes have already brought up the same situation.

The psychopathologist comes to the same problem from the other side; dealing with disorders, which consist in a maladaptation of the patient to his life situation, he finds that in many cases heart symptoms are prominent. He meets these symptoms in states of morbid anxiety, and in various forms of psychoneurotic invalidism. In the anxiety neurosis the whole symptomatology may be dominated by cardiac symptoms; pseudo-anginous attacks are familiar. There is good reason to look for an explanation of these attacks in conflicting trends of high emotional value or in the actual sex life of the patient.

Even though these complex factors may be the basis of the tension in the patient's life, and of the resultant neurosis, there remains the problem why in one patient the symptoms are cardiac, in another respiratory, for example, asthmatic episodes, and in a third, gastro-intestinal. The psychopathologist, analyzing the complex interplay of forces which make up the patient's adjustment to his environment, that is, his behavior, asks the internist what are the physiologic conditions that make an emotional strain hit one man's heart and another man's stomach. Has the former patient a special type of inferiority of the cardiovascular system, quite independent of instinctive or emotional demands, or are the cardiac symptoms altogether dependent on an unsatisfactory instinctive or emotional life, or in most cases are both factors involved, on the one hand a cardiovascular system constitutionally oversensitive or of low resistance, and *on the other* an instinctive or emotional life that involves a good deal of tension?

In making an intensive study of the heart mechanism in these cases, the internist will contribute much to our knowledge *of the psychoneuroses*. The aim of this paper is, however, to emphasize the other aspect of this collaboration, *namely, the place of the psy*chopathologic examination in the total clinical rec of these heart cases.

*Owing to lack of space, this article is abbreviated in *The Journal* omission of a tabulation of neuropsychiatric data. The complete cle appears in the reprints, a copy of which may be obtained on cation to the author.

This communication is based on a group of cases studied in the ovascular service of the U. S. Army *General Hospital No. 9,* wood; more than thirty patients were referred for study by Major ody, who chose them out of a service of about ninety patients. paper is published in the hope of suggesting a certain *line of inves*ion, and not with the view of presenting conclusions.

may be illustrated by the fact
dumb by a situation that causes
ow to give way; the difference in
by the fact that the *man* is struck
by a situation that affects others only
mild inhibition of speech, although in common
guage we use the same descriptive term "struck dumb" (compare the word "stupendous"). Most of us soon recover normal control of our limbs after a terrifying experience, but in some the loss of utilization of the limbs may last for weeks or months. Thus functional aphonia and paraplegia are not adequately explained by a mere reference to the situation, the precipitating and the present fostering situation (safety, luxury, laziness, glory), but require some study of the personality in which they have developed.

The same factors have to be considered in dealing with symptoms belonging to the sphere of the vegetative nervous system. The organ that is specially responsive, the degree to which the organ is affected and the duration of the disturbance may vary from individual to individual.

The persistence of cardiac symptoms after a terrify-
g experience may well be due to a constitutional
iosyncrasy or acquired inferiority, owing to which the regulating mechanism of the heart takes considerable time to regain its equilibrium or never does regain it.

ACQUIRED SENSITIVENESS

The very important general principle must be referred to, that every experience tends to modify the later reaction of the organism; after an infection the patient may be left with increased immunity or in an anaphylactic condition, liable to succumb to an apparently trivial invasion; the individual may be sensitized so that he reacts with special intensity to very small doses of a foreign substance.

The same acquired sensitiveness is seen in relation to more complex stimuli; the soldier who has been unnerved by his experience of high explosives may find later that he reacts with extreme sensitiveness to abrupt noises, and in this reaction cardiac symptoms may predominate.

CASE 15.—A private, aged 20, enlisted at the beginning of the war and went through severe training without symptoms; just before going into the trenches he felt unable to hike, and on his first experience of shell fire he was quite unnerved. At each period of firing his heart would flutter, his knees give way, and he had to sit down; he was sent to the rear. At various hospitals the diagnosis of serious heart disease was made, and he felt that he was doomed. On the voyage home two shots were fired; the patient was so sensitized that he was unnerved for the day; it started the heart pains, and he could not sit down but moved about. At U. S. General Hospital No. 9, the physical status was: "Heart normal in size, left border inside nipple line. Sounds perfectly normal. Soft cardiorespiratory murmur in pulmonic area." It was noticed
hat the patient was dyspneic under the mildest series of drill
xercises for the cardiac cases.

The complexity of the problem of many heart cases
ell illustrated by this history. The first indication
ble was an inability to hike shortly before his
vas due to enter the trenches; the next fac-
terrifying bombardment, to which the
more poorly than his comrades,
his previous history had indicated
than the average; the next
he was stamped with the
nd carried with him all the time the feeling that he might last only six months, in fact, might drop dead at any moment. On this account he never went out alone, haunted by the fear of a catastrophe.

Other factors may also be of some moment, if not in this case, at least in similar cases. The patient had deliberately enlisted, he was willing to do his duty, and officially wished to return to France; but beneath his official attitude was a strong emotional undercurrent of a different nature; he had been glad to get back from "that awful country," old and dilapidated and unintelligible, for which he said he "would not give 15 cents."

This repugnance or repressed fear may in some cases not be irrelevant in discussing the persistence of symptoms:

> Present fears
> Are less than horrible imaginings;
> My thought, whose murder yet is but fantastical,
> Shakes so my single state of man, that function
> Is smothered in surmise.

As far as the vegetative nervous system is concerned, present fears and horrible imaginings and memories may have equal value, and it may make no difference whether or not our pride bars these fears from consciousness.

The patient was easily startled, had been upset by target practice on the ship, and reacted vividly if a door was banged. Such reactions are intelligible because the stimulus reproduces in kind if not in degree the original upsetting stimulus. In other cases the stimulus produces a reaction which is not merely excessive, but which seems to bear no intrinsic relationship to the stimulus; the stimulus may derive its value altogether from its previous association with important emotional experiences, even though the memory of the latter has been more or less repressed from consciousness. Anything that tends to reactivate the memory of the initial painful experience may have a disturbing influence on the vegetative nervous system, without consciousness necessarily being aware of it.

This is in line with what we know of the "conditioned reflexes" of the Russian school; the natural reaction of the dog to food exposed includes salivation, an innate and fundamental reflex; by sounding a musical note before the exposure of food on a few occasions one can develop salivation as a response to the musical note, even in the absence of food.

Just as in this conditioned or acquired reflex the mechanism of salivation is touched by a stimulus that has no intrinsic relationship to salivation but only a relationship based on individual experience, so with regard to the mechanisms that regulate the heart: they may be touched by stimuli whose dynamic value rests on associations that it may take some skill to trace.

From the point of view of treatment these considerations may have some importance, and a review of the personal situation with the patient may well supplement the muscular training he receives. Beneath the quite correct surface in the patient just referred to, with his willingness to resume combatant duty, was a latent repugnance to this return, a feeling of sensitiveness owing to having broken down and as to the opinion of others, a vague tendency to justify himself and therefore perhaps to stress unconsciously his cardiac discomfort and disability; at the same time he was still weighed down by the sentence passed on him in France when he was diagnosed as having heart disease.

May it not do such a man good to let him realize that his latent shrinking from battle experience is natural and can be frankly admitted, that no one judges him on that score, that there is therefore no necessity for any special justification, as by invalidism? May not this ventilation of obscure depressing thoughts contribute something to the reestablishment of the cardiac equilibrium and reinforce the influence of the physicians' confident assertion, based on accurate examination, that the heart is essentially sound and simply needs to be toned up?

The study of a selected group of cases from this point of view would be a useful contribution.

A case similar to the one just discussed was that of a private, aged 20, who had gone through hard training in France, falling out only a few times. After exposure to high explosives he became very nervous, reacted vividly to every explosion, felt weak in the knees, and his heart fluttered. He was slightly gassed, was diagnosed as having "tonsillitis and bronchitis," and later "heart trouble." On the voyage home he reacted excessively to some target practice. At U. S. Army General Hospital No. 9, his case was diagnosed as "effort syndrome."

These two cases bring up the question of the relationship of similar heart cases to cases of war neuroses (the term "shell shock" should be strictly tabued; scientifically it is of no value, and practically it gives the soldiers a wrong attitude toward exposure to shell fire, and its results). Do patients like the two mentioned above have a latent cardiac inferiority, not elicited by the tests of peace nor by the ordinary mechanical demands on the heart, but elicited by the severe emotional demands of the field, while in the war neuroses the patients have other types of sensitiveness, their weak spot lying in the motor system or elsewhere? With this conception, two factors have to be studied in each case: 1. What is the intimate mechanism of the cardiac inferiority? 2. What are the more complex factors, emotional and situational, that precipitate and foster the symptoms?

Cases of the foregoing type might for the convenience of further study be grouped from the special standpoint of this article under some tentative head such as cardiac sensitiveness or inferiority of instinctive or emotional response, unless it is clear that the syndrome is intelligible on the simple level of physiology, and does not require the introduction of the more complex biologic factors, instinct and emotion. From the point of view of prophylaxis or the elimination of unsuitable recruits, it is important to note that in the foregoing cases nothing in the history previous to the actual breakdown would have made the examining physician suspect a latent inferiority.

Among the patients examined, a considerable group presented in addition to their cardiac inferiority a variety of anomalies, constitutional or acquired, sufficient to deserve careful study and an accurate formulation. For convenience of reference these cases are here roughly grouped as cases of constitutional inferiority.

DISORDERED HEART FUNCTION IN THE SETTING OF CONSTITUTIONAL INFERIORITY

The term "constitutional inferiority" is vague and without definite connotation; for that very reason it may be used to denote a very heterogeneous group of persons who have perhaps only the one factor in common that biologically they do not have from the start the necessary stuff for a satisfa[illegible] FACTORS UTILIZED [illegible] demands of the environment.

It is true that many diseases, based on [illegible] seem to be inferiority of one organ or system, prevent some, to [illegible] vidual's attaining average efficiency; but [illegible] tement as diseases the general term "constitutional inferi[illegible] is quite inadequate. They are sufficiently specific to be discussed in relation to the special systems, hemopoietic, gastro-intestinal, etc. The term "constitutional inferiority" may then be reserved for the conditions in which the inefficiency of the individual is based on less well defined disorders. At the same time, in each case it is the task of the physician to define as clearly as possible the special nature of the inferiority, and to try to establish the fundamental factors involved.

In patients with disordered cardiac function, who show a more diffuse constitutional inferiority, the problem will arise as to the relationship of the cardiac symptoms to the other manifestations of the inferiority. Are the cardiac symptoms merely manifestations parallel to those of the other systems, are they more fundamental, showing a specific and disproportionate involvement of the cardiovascular system, or are they perhaps to a certain extent secondary to other factors, such as those involved in the complex organization of the instinctive and the emotional life?

Thus a lack of virility and efficiency might well be secondary to an inferior cardiovascular apparatus; but on the other hand much cardiac discomfort and irregularity might be explained by the undue demands made on the heart by a very unstable or oversensitive emotional life, or by a sexual life which, owing to the constitutional inferiority of the patient, was not subjected to normal control.

TYPES OF CONSTITUTIONAL INFERIORITY

The variety of the problems presented by these cases may be illustrated by the material found in the thirty-three patients examined. Seven of these patients (including one from another service) may conveniently be discussed from this point of view. A brief survey of these patients shows that their constitutional inferiority may be referred to three types:

1. An inferiority manifested in prolonged physical invalidism, with little or no definite intelligence defect.
2. An inferiority in which defective intelligence is a prominent factor.
3. An inferiority in which the instinctive and emotional life is of poor quality, while the intelligence is fair.

It may well be that in these subgroups the rôle played by the cardiovascular system is by no means identical, and it will be of interest to make more precise the exact contribution made by the cardiovascular system to the clinical picture. The physical invalidism of the first group may by careful laboratory and bedside studies be withdrawn from the vague group of constitutional inferiority and be formulated in more precise and specific terms. In many of these cases the sequence and mutual connection of the data are not easy to trace, and problems arise such as the rôle of infections, of hyperthyroidism, of exogenous poisons, such as nicotin, etc.

In addition to the purely clinical aspect of these cases, one has to consider the military and reconstructive aspect. With regard to the possible eventual [illegible] to gi[illegible] by the f[illegible] for foreign or domestic service, [illegible] by a s[illegible]em of reconstruction, the physician [illegible] consider more than the cardiovascular aspect [illegible]se, and in estimating the optimal output of [illegible] that may be expected from the patient, a [illegible]ologic analysis is a necessary datum. It is also worth noting that much of the material that is unsuited for military service might possibly be eliminated by the examining boards, if their attention were specially called to the group and if they were allowed to disqualify a registrant owing to the cumulative effect of a variety of symptoms, *no one* of which by itself disqualifies the registrant.

A brief summary of these seven cases may be given.

Physical Invalidism.—Three cases are representative of this type:

Case 16.—A. B., aged 25, "unhealthy for five years," had been accustomed to guard his health, and eschewed wine, woman and tobacco. Five years previously he had felt too weak to walk; he fainted on inoculation and on venipuncture; he was unable to stand up under drill. His case had been diagnosed as "tachycardia, simple chronic myocarditis." He actually presented the effort syndrome. The patient never had been aggressive, but had drifted along in civil life in a passive, invalid way; he had never had any surplus energy and was frequently unable to go to work. In addition to the general weakness and cardiac symptoms, he had gastro-intestinal symptoms.

In this case the respective rôle of physiologic inferiority, of habit and of personality have to be weighed. The history of the patient would indicate his complete unsuitability for the Army, and the problem of treatment involves attention both to his physique and to his morale; the degree of improvement is no doubt strictly limited by the meager nature of his constitutional assets.

The exact nature of the inferiority of the cardiovascular apparatus in the setting of such a case is a problem of interest. In the following case the personality was somewhat more aggressive than in the previous case:

Case 1.—Private C. D., aged 23, had had night terrors and enuresis in childhood; there had been an early diagnosis of heart disease, because he turned blue easily; the mother was oversolicitous. For many years he had thoracic pain and discomfort, and was on this account irregular at work. He was unable to stand the usual training. In France, his case was diagnosed as "myocarditis, postrheumatic"; in U. S. Army Hospital No. 9, "heart normal: neurocirculatory asthenia. Marked vertebral deformity, faulty posture, general asthenia."

In this case the vertebral deformity and resulting posture furnish a more definite basis for the invalidism than was present in the preceding case; while the patient had shown more virility, and had enlisted. He had been rather discouraged by his physical deformity.

For the management of this case a due appreciation of the rôle played by the physical inferiority and by the personal reaction of the patient to his inferiority is important; one must both realize that the patient has his own special limitations, and encourage him to work up to the level of these limitations.

The same situation is illustrated by the following:

Case 10.—Private E. F., aged 23, had made poor progress at school. He was in the third grade at 16, and had nocturnal enuresis until 18. There was a history of occasional fainting attacks between 10 and 12. From 18 to 23 he spent the summers as deckhand on lake steamers, and spent the winters in a semi-invalid way on the farm. He had chronic trouble with his back and recurrent gastric symptoms. He felt weak about the knees. On entering the Army he was unable to support the drill; later he developed pneumonia; on his recovery a partial thyroidectomy was done.

In this case cardiac symptoms were not in the foreground, and the patient presented a diffuse inferiority both physical and mental; the inferiority can no doubt be formulated in much more specific terms.

A patient from another service presented an invalidism in which gastro-intestinal symptoms were more prominent:

Private C. H., aged 27 (the case is not included among those briefly summarized in the tabulation), had been brought up in Russia as a delicate child, and was illiterate. He had nocturnal enuresis till 12; eschewed wine, tobacco and woman (save for one attempt); came to the United States at 19, and managed to support himself by peddling. There was a vague history of stomach trouble for five years. The patient lived on a liquid diet. There were unconvincing complaints about his eyes, which were not improved with glasses. He had no recreations and no initiative. Under drill he immediately collapsed; his Army experience was purely a hospital one. His official assertion of cooperation was, "I like the army; I want to fight for my country" (sic), but he intends to leave it as soon as peace is declared.

Intelligence Defect.—Even in the first group, reference was made to the mental level of some of the patients; for example, Private E. F. (Case 10), in the third grade at 16 (but in a backward farming community), was of somewhat inferior intelligence; but the physical invalidism of these patients was the prominent element in the clinical picture. In the following two cases there was no diffuse physical invalidism, but the constitutional inferiority showed itself in the intelligence and general level of adaptation (e. g., economic) of the patient:

Case 3.—Private I. J., aged 22, as a child had night terrors; chorea from 10 to 12; a poor school record, at 16 being in the fourth grade. He had always had a restless disposition (choreiform reaction?) and auto-erotism with slight hypochondriacal worry. He was very lazy and had no special plans in life. He was extremely ignorant of general topics, and showed little interest in the newspapers. He had mitral stenosis and insufficiency.

In this case we have to deal with an organic heart disorder in a man of poor constitution; the general constitutional inferiority has no special relationship to the valvular disease, although in making plans for his later employment, both factors must be considered. This case, as a control, may warn us in cases of disordered action of the heart against linking up the cardiac symptoms too closely with the other constitutional or acquired anomalies, without very close scrutiny. Both organic and functional disorders may develop in individuals of poor constitution, but these disorders may have a very specific mechanism to which the other constitutional traits are more or less irrelevant.

Case 2.—Private K. L., aged 28, presented a family history in which the maternal grandfather was insane, the maternal grandmother had a terminal psychosis, and the mother was hysterical. Since boyhood he had had respiratory trouble (asthma?); he had occasional night terrors and somnambulism as a child, and nocturnal enuresis even up to the present. At school he was in the eighth grade at 18; he was inefficient, and worked three years for an undertaker for $9 or $10. On entering the Army he was unable to stand the training. The diagnosis was neurocirculatory asthenia.

Inferiority of the Instinctive and Emotional Life.—The following case illustrates a type of inferiority which is less likely to be recognized by the examining boards and in which disciplinary measures may be taken in ignorance of the lack of full responsibility of the man punished. The ability to talk plausibly covers the inferiority of the machinery that gives a man his energy and his quality ("guts," a popular term indicating an appreciation of the rôle of the vegetative nervous system).

CASE 13.—Private M. N., aged 31, had nocturnal enuresis up to Army life; auto-erotism persisting since 14, very occasional intercourse, and ejaculatio praecox. At 20 he attributed lines on his face to auto-erotism. He made satisfactory school progress, but was shiftless in economic life. For three years he was a janitor at $25 a month. He enlisted in the British army, and later in the American Army. Once he fainted and once fell. On duty his knees would give way, his heart would go fast, and he would pant. The diagnosis was neurocirculatory asthenia.

This man was among the best informed of the soldiers examined, but he was the butt of the others, and his history indicates the inferiority of his instinctive life, the lack of driving force, the tendency to drift along in a shiftless way at a low economic level.

CASES WITH EPILEPTIFORM MANIFESTATIONS

Out of the thirty-three cases tabulated, three presented epileptiform symptoms. One of these cases was a definite epilepsy on the basis of an organic brain disease which had been responsible for focal attacks since the first decade of life.

One patient had recurrent migraine headache with hemianopia.

CASES WITH A HISTORY OF NEUROTIC TRAITS

The following patient is of considerable interest; although in adult life he had not shown any overt nervousness, the family history and his reactions as a child would suggest a latent sensitiveness of reaction.

CASE 20.—Private O. P., aged 24, had a maternal grandmother who committed suicide, and a brother who died insane. In childhood he had night terrors, somnambulism, occasional spasms up to 5 years, and nocturnal enuresis till 7 or 8. He had been a timid child. He stood the drill all winter in the United States, but in France soon developed shortness of breath. The cardiac diagnosis at U. S. Army General Hospital No. 9 was somewhat obscure; sinus arrhythmia, cardiac hypertrophy. This case should be compared with Case 4 and also Case 8, in which there is a definite valvular disorder.

UNCOMPLICATED CASES OF DISORDERED HEART ACTION

The foregoing brief summaries may suffice to demonstrate that in many cases with disordered heart action a variety of complex factors, involving such elaborate units or integrations as instinct, emotion and personality, have to be considered. On the other hand, in a great number of cases there is nothing to suggest the importance of these factors; in such cases the problem seems to be a rather specific physiologic problem. In these cases there is no evidence of constitutional inferiority of any type, no neurotic traits, no anomalies in the instinctive life, no important personal conflicts, no history of sensitizing emotional experiences, no fostering situation.

In this group the internist can go boldly ahead with his detailed researches, without feeling that the key to the disorder may be in some factor which from the very start he has discarded. The internist will have here the last word to say, while the psychopathologist has nothing to contribute.

CASE TAKING AND PERSONAL FACTORS UTILIZED IN CLINICAL RECORD

In view of the foregoing data it would seem to be desirable in many cases, and essential in some, to include in the clinical record a summary statement as to the personality of the patient, and as to any experiences and situations that seem to have a direct bearing on his disorder.

In order that the necessary ground may be covered in a systematic way, the following outline is submitted as a guide in making the clinical record, not as a questionnaire to be rigidly followed.

A few preliminary remarks may be of use. The purpose of the examination is to determine (1) whether constitutional factors have played a part in the sickness, (2) whether past experiences have conditioned the present reactions of the patient in a morbid way, and (3) whether present instinctive conflicts or a personal situation of much emotional value may not be contributory causal factors.

REVIEW OF THE CONSTITUTIONAL TRAITS OF THE PATIENT

As to the constitution, or innate equipment of the individual, that can be estimated partly by a study of the stock from which he has sprung and partly by a study of his early reactions to the tests of life, before training and experience have come to play a preponderant rôle.

One will pay special attention to the presence in the family tree of insanity, epilepsy, migraine headache, alcoholism or similar maladaptation, hysterical manifestations, invalid type of reaction, eccentric disposition, and mental defect (from the point of view of intelligence, of emotional stability, or of balanced output of energy).

The early reactions that are suggestive of a special sensitiveness or neurotic instability, especially if they are very frequent and exist in combination, are night terrors (pavor), bed wetting (enuresis nocturna), somnambulism, chorea (a rather heterogeneous group in which toxic and constitutional neurotic factors have to be carefully disentangled), convulsions (tetany, epilepsy), tantrums and exaggerated emotional reactions.

In addition to the nervous stability of the patient one wishes to estimate his general level of efficiency, and to note any serious variation from the average. The level of intelligence may be estimated by the school record, the wage-earning capacity, and the answers to standard questions on general information. Whether the patient has shown any special abnormalities in his emotional life or in his general activity will be found by reviewing his behavior to his comrades, his interests, his reactions, his steadiness at work, and his responsiveness to standards of honesty, truth and decency.

There is a tendency to emphasize the type of constitutional inferiority which shows itself in subnormal intelligence, and to overlook those cases in which the intelligence is adequate but the patient may be perhaps unstable, volatile and superficial; or overactive, enterprising, but lacking in judgment; or unaggressive and timid, lapsing easily into invalidism; or intelligent, and efficient in many ways but not responsive to important moral standards. To formulate the various ways in which an individual may be subnormal in virtue of a defective innate equipment would be an elaborate task; the foregoing remarks merely illustrate the method of estimating the quality of the patient's whole machinery for reacting to the environment.

HISTORY OF THE PATIENT WITH SPECIAL ATTENTION TO EXPERIENCES LIKELY TO HAVE SENSITIZED HIM TO SPECIAL TOPICS

No systematic outline can be given to guide the examiner in this review; so much variation exists in human life that it is not possible to cover all the possible situations that may have influenced the patient's later reactions. One may refer to a few of the more frequent factors by way of illustration:

1. The early reaction of the child to the authority of the father may influence permanently the individual's reaction to all authority, and may be a determinant of an unusually submissive attitude, or on the other hand of an obstinate resistance to authority in all its forms (intellectual, religious, political, military).
2. An early feeling of inferiority in relation to school efficiency or physical endowment or personal traits may bring about an undue sensitiveness and shrinking or, on the other hand, an apparent self-confidence and overassertiveness which is merely a cover for the underlying lack of confidence.
3. Poor methods of dealing with the incipient sexual instinct, with the marked emotional value given to this subject, may seriously complicate the ability of the adult to meet this test in a frank and satisfactory manner. The adult life may accordingly be made unnecessarily difficult because the individual has been sensitized to this topic, has become accustomed to deal with it in a muddled way, and has not come to a frank, independent realization of the whole situation.
4. Any episode of great emotional value may leave the patient permanently modified in his reaction to similar stimuli; just as the soldier, unnerved by high explosives, may for a considerable period be oversensitive to loud and abrupt sounds.

It is important, therefore, to note any striking experiences in the life of the patient, and to consider whether they may not throw light on present symptoms in the way suggested above.

The memory of an experience may have disappeared from consciousness, while a certain emotional attitude with its component physical symptoms may persist. We may have a feeling of dislike for some place or person, without being able to state what past experience or what likeness is at the basis of this attitude. In some the physical component is disproportionately prominent; after a disgusting experience a patient may, perhaps after a considerable interval, develop an intractable vomiting. A terrifying experience may be eliminated from the memory of the patient, except perhaps in dreams; but the tremors, weakness, palpitation, etc., show that his system still vibrates to the experience.

ANALYSIS OF THE SITUATION

The key to some disorders can never be found so long as the physician confines himself to the study of the patient, no matter how intensive that study may be. The headache, backache, weakness, insomnia, timidity, etc., that may follow a railway accident sometimes disappear rapidly when compensation is given in the form of a lump sum, instead of a weekly pension lasting as long as the disability. The change in the method of compensation does not alter directly the joints or other structures of the body; it creates a different situation. It creates a situation that stimulates effort, replacing a situation that puts a premium on feelings of weakness and discomfort. Many forms of invalidism, although deplored by the patient, still have their own gain, bring in certain immunities or privileges and enable one to maintain one's self-respect, to secure sympathy, and to postpone the necessity for grappling vigorously with the actual difficulties of life.

In estimating the degree of disability caused by cardiovascular symptoms, one must consider them in relation to the whole situation, must see whether they play a rôle in the subconscious adaptation of the patient, and must find whether the situation can be altered so that anything that tends to foster the symptoms is eliminated, and everything that can stimulate the healthy activity of the patient may be utilized.

The military situation is obviously an extremely important factor; the physician tries to stimulate the aggressive, healthy trends of the patient, when as a matter of fact the restoration of health leads to the trenches and the toil of war, for which the patient has a deep-seated repugnance, however nobly he may deliberately accept his share in the unwelcome tasks. His conscious, official self is loyal to his civic duty, but his subconscious and instinctive self shrinks from destruction. Any disability is in a way a godsend; the cheerfulness of the wounded when they have got "a Blighty one" is notorious. The physician has to recognize this situation frankly, and to consider by what methods he can counteract any enervating influences, keep burning the flame of resolve, and maintain the morale of his patients. Morale is as important in the hospital as in the trenches; it should be the keynote of reconstruction as of destruction.

The military situation, however, is not the whole story; as in civil life we cover up all the intimate causes of our nervous invalidism by the conventional explanation of overwork, so the stress and the strain of war are apt to be utilized as a blanket explanation of disorders of subtle origin. It furnishes the welcome impersonal formulation; but the soldier has as complex a personality as the civilian, and it is often in the complexities of personal conflicts and difficulties that the explanation of obscure symptoms must be found. The home situation, the attitude to parents, sweetheart or wife, memories of the past, repressed desires and hates and jealousies—these are not irrelevant to the symptomatology of disorders of the heart; language bears witness to that with "heart burning," "heart sick," "his heart was in his mouth," "stabbed to the heart," "fear in his heart," etc.

To analyze the contribution made to the symptomatology of heart disorders by such factors no doubt requires experience, but an open mind and a nice intuition will solve many individual problems with benefit to the patient.

Auscultation.—In auscultation of the chest, it is important to secure close and accurate apposition of the stethoscope to the skin. The object of this is to eliminate those adventitious sounds which are introduced either by a slight skating movement of the instrument on the surface of the chest, or because the whole circle of the chest piece is not making contact with the body wall. Again, it is in order to exclude extraneous sounds that the careful practitioner chooses thick-walled tubing for his instrument, and is particular to detect the first sign of any perishing of the rubber near its junction with the metal and to remedy the fault. (By their stethoscopes ye shall know them).—Sir Thomas Horder, *Practitioner.*

THE MANAGEMENT OF CERTAIN INTRACTABLE LID CONDITIONS *

MELVILLE BLACK, M.D.
DENVER

Seborrheic forms of blepharitis marginalis of long standing are not always easy to dispose of by the correction of errors of refraction and the application of ointment of yellow mercuric oxid. There are probably few present who have not been sadly disappointed in their expectations of a cure from this treatment. In many of these cases there is an underlying systemic cause which is often hard to find and, when found, harder to correct. Long years of uncorrected eye strain, bad hygiene and improper use of food and drink have brought the patient to such a state that our ministrations can at best only partly restore the eyelids to a normal appearance. After the disease has become chronic, it resolves itself locally into a chronic infection of the follicles of the eyelashes. I am inclined to think that it is at first a nutritive disturbance and that the infection is secondary. If several lashes are pulled from such a lid, in a mild state of blepharitis, it will be observed that some of them come away more easily than others and that their roots are black. The lashes, if left alone, would fall out in a few days' time. This disturbance of nutrition may be occasioned by errors of refraction which lower the resistance to infection, or some physical state which acts as the predisposing cause. The correction of the error of refraction and the use of yellow oxid ointment will generally bring about a temporary improvement, but, in the stubborn cases we are considering, the underlying general constitutional cause must be eliminated. In many instances, I do not consider myself competent to do this and prefer to refer the case to an internist in whom I have confidence.

In our altitude, anemia is most frequently found as the underlying constitutional cause. These blepharitic subjects are usually washed-out looking individuals, in whom an examination of the hemoglobin percentage shows it to be low; possibly also the red cell count is considerably below normal. The usual method of giving iron by mouth is of doubtful value, while iron and arsenic, or citrate of iron and manganese given hypodermically, are definite and prompt in their results. There are so many physical disturbances to be considered that we may dismiss the subject with the statement that each case must be studied carefully, and when abnormal physical states are discovered, an intelligent attempt must be made to correct them. I confess that this is often easier said than done, but if the patient is a child, as is usually the case, and the cooperation of the family can be obtained, not only brilliant results follow, but the child has been started on a new road to health and well being.

CHRONIC CONJUNCTIVITIS

In many instances this affection is a very simple affair and responds to a number of different stimulating and astringent remedies. Every now and then, however, we see a case which does not differ from the others in appearance, but which does not respond to local treatment. There is some reason, of course. Errors of refraction have been corrected, but the patient continues to complain of irritation, and the palpebral conjunctiva shows marked signs of being inflamed. A pathologist is called in, but almost always reports, "No growth and no bacteria found." I have worried over many of these cases and still continue to do so. Many of the patients are robust, and nothing can be found physically wrong with them. Others are found to have various systemic disorders, but whether more than are to be found in the average of individuals is a question. It is proper to attempt to correct these physical disabilities, because in a large number of the cases the conjunctivitis is secondary to some physical defect. In a small minority, however, nothing seems to do any good, either in the way of local or general treatment. I hope the discussion will bring out the remedy which I am unable to supply.

EPIPHORA

The overflowing of tears and the frequent filling of the eyes with water is a common symptom in elderly people. It is also frequently seen in comparatively young people who have spent a large part of their lives outdoors. It is always necessary to exclude dacryocystitis by syringing through the duct before it is possible to make a diagnosis of simple epiphora. In senile epiphora the cause lies in the flabbiness of the skin of the lower lids and relaxation of the orbicularis muscle.

The puncta of the lower lids, if inspected closely with a binocular head loupe, are visible without the necessity of making traction on the lower lids. The normal punctum is not visible, being turned in against the eyeball. A certain amount of eversion will not disturb the capillary attraction of fluid, but just as soon as the eversion has passed beyond a certain point, there must be a lake of tears formed before the fluid will flow into the punctum. The efforts of the patient to prevent the overflow by wiping the eyes is usually accompanied by a movement of the handkerchief outward and downward. The relaxed lid is mechanically everted more and more by this faulty wiping until the punctum is found displaced completely outward on a rounded, thickened lid border. It may be so far out of position as not to be functioning at all. From this stage, it is only a step to complete ectropion of the lower lid. The overflowing of tears causes a chronic dermatitis of the lower eyelid and adjacent skin. This leads to skin contraction, and the lid border is pulled on as though contractile collodion had been painted over the skin surface.

In the younger subjects with weather beaten skins, the same process takes place. In these cases, however, the tightly drawn skin over the cheek bones is the primary cause of the outward displacement of the punctum. As soon as it is everted to a position in which the lake of tears forms, the wiping of the eyes and the irritation of the skin from the water flowing over it rapidly causes ectropion of a most pronounced character. I have seen many cases from our cattle ranges in which the fornices of the lower lids were completely exposed as a red granular looking surface, presenting a most repulsive appearance. I have frequently noticed that these very bad cases were in "sandy complexioned" people.

The management of simple epiphora, whether the patient be old or young, depends on the extent to which the puncta are everted. If they are slightly everted, the patient should be directed never to make dragging movements on the lower lids when wiping

* Read before the Section on Ophthalmology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

the eyes. He should be taught always to make pressure toward the inner canthi. Facial massage with cold cream should be practiced each night for ten minutes, the movements of the tips of the fingers being directed over the skin of the cheeks toward the inner corners of the eyes. Correct wiping of the eyes and this daily massage will usually restore the puncta to their normal position.

If the eversion has passed beyond the stage at which this simple treatment will replace the puncta in their normal positions, more radical measures are in order. It has been my practice to dilate the punctum and then introduce one blade of a pair of Stevens tenotomy scissors vertically down to the bottom of the punctum, the other blade being directed toward the eyeball, and to make a snip of the lid tissue between the two blades. *This cut must be kept open by daily* breaking its lips apart with a punctum dilator, until it remains open. This causes a lowering of the punctum so that the tears will run into it before a lake has formed.

Another method that has given me much satisfaction, especially when the patient lives out of town and is in a hurry to get home, is, after making the vertical snip, to pass one blade of the scissors about 2 mm. along the canaliculus and make a snip, then with a pair of forceps pick up the little triangular flap which lies between and cut it off. This leaves a triangular hole on the inner surface of the lid. Its edges heal in a few days, and usually there remains a large artificial punctum, the lower margin of which gathers in the tears before a lake has formed. No after-treatment is required, as its edges are far enough apart to prevent their healing together, as is the tendency when the single vertical snip is made. In the extreme cases of eversion, in addition to the measures already outlined, I have found Ziegler's method of cautery puncture of the conjunctiva and tarsus of great value. If the entire lid is everted, a row of cautery punctures about 4 mm. apart will have to be made. If only the inner half of the lid is everted, two or three punctures in the everted portion of the lid will suffice.

CICATRICIAL TRACHOMA

In Colorado we are fortunate in having little trachoma to deal with, but we do have some. The cicatricial forms are just as bad with us as elsewhere, or worse. This may be because our bright sunshine and dust cause the patient great discomfort. Once pannus and recurring corneal ulceration have begun, it is only a matter of time until the patient is almost blind. If anything can be done to cause the pannus to disappear the corneal ulceration will stop, and it is surprising to what an extent these corneas will clear. Even though the corneas are hopelessly damaged, the photophobia and general ocular irritation will be so improved that the patient is comfortable and most thankful. Plastic lid surgery has its place in bringing about this result, but, above all, it seems to me that the diseased tarsus must be excised.

I believe that Kuhnt was right when he said, "The excision of the tarsus is the last word in the management of cicatricial trachoma." The operation, as performed by Kuhnt, Wood and others, is a most formidable procedure because of the sutures. The patient is rendered very uncomfortable for a week or longer, and the removal of the sutures is often difficult. It is a hospital operation because a general anesthetic is necessary.

Some years ago, I saw L. Webster Fox perform an excision of the tarsus, using no sutures. It was so simple that I went home and tried it, and since then I have never used a suture after excising the tarsus. Instead of a hospital operation, it becomes a simple office operation and is performed as follows: A 2 per cent. solution of procain (novocain) is injected through the skin of the upper lid into the tissues overlying the tarsus at the inner, outer and middle portions. The lid margin is then grasped with a pair of tenaculum forceps and everted over a horn spatula, and more of the same anesthetic is injected into the conjunctiva and tarsus in a few places. To control bleeding, the lid is pulled tight over the spatula. An incision with a knife is made through the conjunctiva and tarsus parallel to the lid border; and about 2 mm. from it, another incision is made at the upper margin of the tarsus. The outer angle of this island of tarsus is picked up with forceps and the tarsus dissected away with curved scissors. One or two arteries spurt a little, but are easily controlled by torsion. The operation is over. The lid is turned back into position. Hot applications are made until all bleeding has ceased. The eye is filled with an ointment of mercuric chlorid and petrolatum and bandaged, and the patient is sent home.

I usually do one eye at a time. The next day the eye is dressed and not closed after that. The patient walks away with the eye open and is no more inconvenienced than before the operation. In a few days the lid is everted to see if exuberant granulations are forming. If so, they are snipped off or cauterized with a silver stick. In three weeks the lid has healed. It is smooth, and the old diseased tarsus which has played so conspicuous a part in causing the corneal disturbance is gone forever. I used to dread to see patients with cicatricial trachoma come into my office or my clinic. I now rather enjoy their coming, for I feel that I have something to offer that will bring results that are sure and swift.

ABSTRACT OF DISCUSSION

Dr. J. Sheldon Clark, Freeport, Ill.: Clamps and other instruments used for holding the lid after it is everted may be discarded for an instrument designed by Stanculeanu of Bucharest. It is something like a lid retractor. The lip of the retractor is cut off, leaving a straight edge that permits one to hook up the lid and evert it. The instrument is put in from above, the lid is everted over the elevator and then is held up in position while proceeding with the operation. It controls the bleeding very nicely, causes no pain and is very satisfactory.

Dr. Oliver Tydings, Chicago: About fifteen or sixteen years ago a man, about 40 years of age, came to me to be refracted. I noted the blepharitis marginalis, and suggested that he be treated. He refused treatment. Five years afterward he came back because he had reached the age of presbyopia and wanted another pair of glasses. He also consented to have his lids treated. The treatment, which consisted of massage, extended over a period of about eighteen months.

Massage was given two or three times a week at first and then at longer intervals, all the follicles were expressed, and then the margin of the lid was painted. Massage, the application of about 15 per cent. of silver nitrate, and the use of yellow mercuric oxid and mercuric chlorid ointment resulted in a good recovery. I have never seen a case that could not be improved. I do not think that there is any relation between refraction and blepharitis marginalis.

Capt. H. B. Lemere, Camp Mead, Omaha: I have used the procedure Dr. Black recommends in trachoma and I can corroborate everything he says about the operation. I modified the operation slightly. I use a lid clamp. By dissecting one end of the tarsus at a time and then moving the lid clamp on to the other end, I can do the operation practically without any blood obscuring the field. The operation can be done quickly and the patient is an ambulatory case.

A REGISTRATION FEE FOR PHYSICIANS *

FRANCIS W. SHEPARDSON
Director of the Department of Registration and Education
SPRINGFIELD, ILL.

At a committee meeting held in connection with the Illinois State Medical Society in Springfield, a prominent member of the society made a speech in violent opposition to a proposal for an annual state registration fee for physicians. His main argument was that medicine, being the oldest and most honorable of the professions, was in a class by itself, and that it was entirely beyond reason to think that the physicians could ever be grouped for registration purposes with architects and barbers, blacksmiths and plumbers, dentists and druggists, structural engineers and veterinary surgeons, all, of course, so he implied, far beneath the physicians in dignity and honor. He was exactly like one who would magnify the "noblesse" and forget the "oblige"; who would stand unmoved when the things he was pledged to defend to the death were insolently attacked. And that is the text for what follows:

The Civil Administrative Code of Illinois specifically provides that the officers of the Department of Registration and Education, under whose jurisdiction the administration of the Medical Practice Act comes, shall be neutrals. The exact language is:

> The Director of Registration and Education, the Assistant Director, and the Superintendent of Registration shall not be affiliated with any college or school of medicine, pharmacy, dentistry, nursing, optometry, embalming, barbering, veterinary medicine and surgery, architecture or structural engineering, either as a teacher, officer or stockholder, nor shall they hold license or certificate to exercise or practice any of the professions, trades or occupations regulated.

The officers of the department approached the work of enforcing the Medical Practice Act without any bias, but, confessedly, with something of the accustomed reverence for medicine as a great and honorable calling, represented by men of far more than ordinary professional ideals. They expected to find a medical nobility, with a lively appreciation of its obligation to protect its honor. They confidently looked to find the drawn sword and the defending shield bearing the significant words, "No one attacks our profession with impunity."

But this is what they actually found, during a year's experience and study:

DISCOURAGING ELEMENTS IN ILLINOIS MEDICAL SITUATION

They found a poorly organized profession, with less than half of its members associated in its state society, and with no clearly outstanding champions ready to tilt their lances against foes of medical honor. The *Bushido* ideals of the sometimes despised Japanese were nowhere in evidence. The unity and professional spirit of other crafts, often ridiculed by physicians as of far lower social standing, were entirely lacking.

They found an army of advertising charlatans, some with fixed offices and others appearing "for one day only," making extravagant claims of curative skill in handling all diseases, specialists in everything, blatant fakers, robbing the poor and the ignorant, preying on the superstitions of gullible foreigners, as bold and daring bandits as ever sandbagged a lone wayfarer at night; and yet unattacked in any effective way by the plumed knights of medical chivalry, but permitted to continue in shameful practices that would not be tolerated for a day by representatives of other professions and trades counted far inferior to medicine.

They found a motley array of so-called "doctors," of every name and cult under the sun; regulars, homeopaths, eclectics, osteopaths, chiropractors, napropaths, spondylotherapaths, mechanotherapaths, neurotherapaths, electrotherapaths, hydrotherapaths, suggestive therapaths, psycotherapaths, naturotherapaths, iridologists, magnetic healers, religious healers, and many other varieties, the list forcibly reminding one of the description which Masson gives in his "Life of Milton" of the sects which flourished in England in the poet's time. After naming a great many, he includes in a sweeping classification the remainder of the some hundred-odd varieties of "fluent, rancorous, inquisitorial and on the whole nasty kinds of Christians." Even such a comprehensive description would hardly include all of the so-called medical practitioners of Illinois, nor would it cover the radicals who oppose all regulation, claiming for the people "the inherent right to choose any sort of a doctor they please, even to 'dope' doctors or Christian science if they want it."

They found chains of doctors' offices, managed by real estate agents or other nonpractitioners and attended by licensed physicians who were paid from $8 a week to $35, with a possible commission of 10 per cent. on all gross business over $500 a week; the manager getting all the receipts, paying rent, furnishing light and providing equipment; the physicians being paid off like barbers or other hired hands on a Saturday night; the offices using common literature, apparently printed by the ton, distributed by hand in mail boxes and front yards, and bearing the name of the doctor nearest the region of distribution, who for himself was unable to read the circular in the language used, and so knew nothing of the glowing promises made to his prospective patients.

They found many doctors alleged to be abortionists, who, when questioned about the wholesale murder of unborn babes, took refuge in assertions of the guilt of all the craft, and claimed that if, in any company of members of the profession, the ancient invitation were renewed, "Let him who is without sin among you cast the first stone," as in the days of old so now, within a short time, no man would be left except the accused and the judge.

They found doctors, all over the state, who were guilty of unethical practices, who were known to be quacks of the worst type, and against whom sufficient evidence could not be secured to convict because of the unwillingness of reputable physicians to give testimony or to encourage deluded victims to give to the department for legal use information given to them in quiet hours of confession.

They found men and women in many places in Illinois practicing medicine without license and defying the provisions of the Medical Practice Act. But they could not secure convictions because regularly licensed practitioners refused to aid, because state's attorneys declined to enforce the laws, and because county medical societies have been too weak or too fearful to demand that such prosecuting officers perform their sworn duty, or too little interested to help in creating public sentiment in support of law and decency.

---

* Read before the Madison County Medical Society at Alton, Ill., Aug. 2, 1918.

The plain, unvarnished, easily supported truth is this: There are more fakers and charlatans in medicine than in all other professions and trades put together. There are more irregular, improper, indecent and immoral things connected with medicine than with all the rest. There is less real reason, so far as conditions in Illinois are concerned, for medicine to claim nobility and plume itself because of its high estate than there is for almost any occupation followed in the commonwealth by the sons of men. There seems to be no medical nobility which feels any obligation. There seems to be no champion, either individual or corporate, that is quick to resent attacks on edical honor. With one exception, not a county ical society in all Illinois has given to the Depart- t of Registration and Education during its first administrative year that hearty cooperation, that united and determined support which is so desirable if its attempts to enforce the Medical Practice Act are to be successful. The exception was the society in St. Clair County, where, as the result of shameful riots which stirred the entire United States, the social forces desirous of the maintenance of law and order were encouraged to express themselves in demands for a general clean up. In this process the department was able to secure in that county ninety-three convictions for violations of various statutes, eight being infringements of the Medical Practice Act. Sixteen cases are still pending. Among the individuals convicted was the notorious Vizgird of East St. Louis who vainly tried to escape the officers of the department and the penalties of Illinois laws by seeking a hiding place in Missouri, but was caught in his old haunts one evening and given his deserts by the court.

Perhaps this is enough of the discouraging side of the Illinois medical situation. But the need of cooperative effort on the part of all interested in better conditions is great. This is a most favorable time for advance movements. The mobilization of our army has emphasized the importance of discipline and respect for authority. The rejection of so many men as unfit to fight for their country has led to much serious thinking on the part of the people. Certain forms of disease have been studied in an entirely new light. The potential soldier who has barred the door of his admission to the Army by venereal disease, contracted by cohabitation with prostitutes, is looked on almost with the scorn that attends the slacker or the traitor. He who has weakened his fighting strength by excess in the use of intoxicating liquor finds the hand of every man against him. Sobermindedness, clean living, unimpaired efficiency are demanded everywhere. The individual who, in any way, contributes toward the restriction of the output of American man power in this critical hour of world conflict has no influence, no political pull, no effective support anywhere. It is the time for the friends of medicine to strike and to strike hard against those of its adherents who drag its honor in the dust. The fact that so many honorable physicians have gone to war, and that so many communities are left to the mercy of the irregular, unethical or illegal practitioner lends added importance to the situation now faced.

PROGRESS IN MEDICAL EDUCATION

Considerable progress has been made in the direction of improved conditions in education. A few years ago Illinois had fourteen medical schools, some of them so poor in quality that a great historic survey declared Illinois to be the plague spot of medical education in America. The finger of scorn was pointed toward Chicago by every one connected with the profession. Now there are but five medical colleges recognized as in "good standing." Each of these five colleges has been visited and inspected by the department during the year, one of them twice. The student records have been searched with care by a special representative of the department. Where irregularities or improper methods have been discovered, the facts have been called to the attention of the officials of the institution affected, and prompt promises of rectification have been made. New rules and regulations connected with the Medical Practice Act have been established and put in force, after a conference participated in by the administrative officials of the department, by the members of the Medical Examining Committee, and by the deans and secretaries of the five schools. Each of the five institutions, through the proper official, has indicated in writing its intention to abide by these regulations thus agreed to. One of these new rules raises the minimal entrance requirement to two premedical years. Future licensees in medicine in Illinois, before being eligible for examination, must have had preparation for active practice represented by four years of high school, two years of college premedical instruction, four years in a medical school and one year's internship in a recognized hospital. Another new regulation provides that each student, at the time of his admission to a medica school, must present a qualifying certificate, issued by the Department of Registration and Education, certifying that all requirements for preliminary educatio have been met. It is believed that this provision wil end forever the most troublesome feature connecte with the regulation of medical schools, namely, th admission of inadequately prepared students, either o conditions or on defective certificates.

Attempts are being made through mandamus pro ceedings to secure the restoration to "good standing of two medical colleges, namely, the Jenner Medica College and the Chicago Hospital College of Medicin institutions which had been declared by the stat board of health to be no longer "in good standing with the licensing authorities of the state. A larg amount of time and attention has been given to th consideration of these petitions. The institutions wer reinspected, one of them twice. Several meetings fo conference were held, attended by representatives the department, administrative and professional, ar by those interested in the colleges. In one of thes conferences, representatives of the office of th Surgeon-General of the United States Army partic pated. It was gratifying to find that their judgme was the same as that given with entire unanimity by th representatives of the state of Illinois, namely, that th institutions should not be recognized. Whether t courts will force an action contrary to the best wisdo of those entrusted with safeguarding the interests the people remains to be seen.

EXAMINATIONS FOR LICENSURE

Examinations for licensure in Illinois are better conducted now than ever before. The Civil Administrative Code provides carefully for the safeguarding of this door of entrance to the medical profession through a committee of five persons, all of whom shall be reputable physicians licensed to practice medicine and surgery in this state, no one of whom shall be an officer, trustee, instructor or stockholder or otherwise interested, directly or indirectly, in any medical college or medical institution. For the purpose of preparing questions and rating papers on practice peculiar to any school, graduates of which may be candidates for registration or license, the director may designate additional examiners whenever occasion may require.

In the March examination a new feature was introduced in the form of a practical test, consisting of one hour with patients in eye, ear, nose and throat; one hour with surgical patients; one hour with diagnosis and medical patients, and one hour in the laboratory identifying slides. Through the courtesy of the officials of the Cook County Hospital, the facilities of that great institution were placed at the disposal of the department. Both examiners and examined entered into the spirit of the new arrangement with hearty interest. The results of the experiment were so gratifying that it was decided to make this a permanent feature of the examination plan. In the June examination the same method was followed, with an unusually large class of candidates, the results again being satisfactory in every way. It has also been determined that no license by reciprocity shall issue hereafter, except after the presence of the candidate before the examination committee and the passing of a satisfactory practical test.

These two advanced movements have placed Illinois in the forefront, since the practical examination for licensure has not made much headway in America. The members of the examining committee have determined to make the entrance into the profession more difficult by closer scrutiny of the written and oral reports of the candidates. They share with other representatives of the department in the earnest desire to make the Illinois license in medicine most honored of all state licenses because most carefully guarded.

REGULATION OF PRACTITIONERS

With conditions in the recognized medical schools more satisfactory than ever, and with the examinations for licensure greatly improved, the next important task of the department is the regulation of practitioners within the state. But here it is beset with many obstacles. Its two principal weapons for warfare are the Civil Administrative Code and the Medical Practice Act. The first confers on it far greater powers than were enjoyed by the former state board of health. The second goes far ahead of any statute heretofore adopted for regulating medicine. Its provisions correct many of the weaknesses of previous statutes. Under it, it is now possible to revoke licenses issued under any preceding practice act, whereas the law which it superseded was powerless over some practitioners. The act also gives larger range in the matter of revocation of licenses, the following nine types of offender being indicated:

1. A person who has been convicted of the practice of criminal abortion.
2. A person who has by false or fraudulent representation obtained or sought to obtain practice in his profession.
3. A person who is a habitual drunkard, or habitually addicted to the use of morphin, opium, cocain or other drugs having a similar effect.
4. A person who has by false or fraudulent representation of his profession obtained or sought to obtain money or any other thing of value.
5. A person who has advertised under a name other than his own.
6. A person who shall advertise or profess publicly to treat human ailments under a system or school of treatment or practice other than that for which he holds a license.
7. A person who has been committed, by the judgment of a court of competent jurisdiction, to a hospital for the insane.
8. A person who is guilty of any wilful violation of the rules and regulations of the Department of Registration and Education governing examinations, or who is guilty of any fraud or deceit by which he was admitted to practice.
9. A person who has been guilty of any other unprofessional or dishonorable conduct.

It will be noted, however, that these provisions have their limitations. For example, the rumor that a physician is guilty of abortion is not sufficient ground on which a license may be revoked. Even the dying declaration of a victim is not adequate. The law provides that the accused shall be convicted, and the presumption is that this means convicted in a court of justice. In like manner, if a practitioner has become insane, the law does not cover his case unless he is actually committed to an asylum. In a recent hearing of the department in Chicago at which some forty reputedly unethical practitioners were summoned, three of these on examination showed clear evidences of insanity, and that, too, to the satisfaction of all the representatives of the department present. But the law does not cover their cases, and they will continue their practice until, by reason of some violent outburst, they at last find their way to the sanatorium where they should now be incarcerated.

The cause set forth in the ninth paragraph covering general unethical and unprofessional conduct has not been considered by legal authorities as in itself sufficiently definite to warrant a revocation of license, although it may well be used in supplement to other charges.

While there are some defects in the law as it is, yet, as has been stated, it is far ahead of anything the state has yet had. The act applies to two classes of citizens: one, the individual who, not being regularly qualified by proper licensure, as provided for in the law, attempts to practice medicine; the other, the practitioner who has been regularly licensed. It might be taken for granted by every one that an untrained individual of the first class should be prohibited from practicing medicine. As a matter of fact, however, in a number of cases in which the evidence has been conclusive, the department has been unable to secure conviction because of the attitude taken by prosecuting officers, some of whom have actually attempted to explain their failure to enforce the law by statements that the provisions of the law are foolish or should never have been enacted. A notable instance of this kind occurred in one county where a retired farmer of considerable wealth and social prominence was known to be treating human ailments at the county seat as a chiropractor, although he had no license whatever so to do. The state's attorney, while not absolutely declining to prosecute, made all sorts of excuses for not doing so, saying that he was too busy with other matters to take up this particular question; so the department was powerless. The folly of such a condition was soon shown, however, by the verdict of the coroner's jury in a certain case in which it was declared that the death of a child had been brought about because of the improper practice of this particular man and another with whom he was closely associated and who likewise was not prosecuted as he should have been.

Another case not unlike this was reported from southern Illinois. An inspector for the department filed an information in the court against a noted chiropractor. The state's attorney of the county delayed action and later wrote a letter to one of the state officials asking him to go to the Department of Registration and Education and induce its officers, if possible, to withdraw the information, when its sworn duty is to follow up the offense with prosecution. It is needless to say that the department declined to take the action requested and that the case is still pending. Many other cases of a similar nature might be mentioned.

The department believes, however, that if it had the hearty backing of all regularly licensed physicians —and with that would come a sufficient public opinion to force all prosecutors to act—it would be able to make notable advances in clearing the state of unlicensed practitioners within a relatively few months.

But the Medical Practice Act was designed in the main for those who have been licensed through the regular processes. There is no doubt that its spirit contemplates that the business of the profession shall be carried on in an ethical manner. It does not reach those who use flamboyant advertisements proclaiming their great skill, but it does give power enough to require the advertiser to keep within the bounds of possibilities so far as his promises to his prospective patients are concerned. It does not reach the itinerant physician who practices in hotels in various places "for one day only," but it does have power enough to require him to register his license in every county where he practices and to restrict to some degree his advertised pretentions. When the itinerant is unlicensed, the law may be readily invoked. A case in point is that of the well-known Rev. Dr. Hawkins who has visited many places in Illinois in recent years. Not long ago he came to Springfield. Inspectors from the department called on him, one of them for physical examination and treatment. When the latter found that the gentleman who tried to use the cloak of religion as a shield to his illegal practice simply rubbed his hands over his victim's body, speaking practically meaningless words as he did so, he swore out a warrant for the arrest of the faker and had the satisfaction of seeing him placed in the Sangamon County jail, where he spent several unhappy days, part of the time as a result of being charged with working a confidence game. However, between 9 and 11:30 o'clock in the morning on which he was arrested, the reverend gentleman had been successful enough in his practice to secure fees of more than $300. This would have been a fair morning's work had he not had the misfortune to be caught by the officers of the law and consequently faced with the probability of being compelled to pay a large fine.

NEED OF ANNUAL REGISTRATION

The department needs another administrative aid, an annual registration, in order that it may be able better to serve the interests of the people and at the same time to protect those rightfully entitled to the honors and the emoluments of the medical profession.

The records show that, under the first medical practice act of 1877, 18,626 individuals were licensed—16,905 by the presentation of diploma, 1,236 by years of practice, and 485 by diploma and supplementary examination. Under the acts since 1899, there have been licensed by examination and by reciprocity 11,310, making a grand total of 29,936. How many of these licenses are active at the present time, nobody knows. The department has no check on them, as it has on licentiates in other lines by means of an annual registration requirement. In 1916 the American Medical Association made a computation which placed the number of living physicians in Illinois at 11,600. Counting for deaths and removals, and estimating additions by examinations, there probably are about 12,000 at the present time who hold Illinois licenses. Ignorance on this vital matter of administration places the department under a great handicap. It does not have any means of knowing where its licentiates are or what they are doing. It receives a daily press-clipping service which helps to some degree in checking deaths and removals. But its inspectors find impostors who are using the licenses of honorable practitioners long since dead; impostors who secured their licenses through fraud; charlatans who are claiming to be authorized representatives of patriotic physicians who are "over there" ministering to the wounded and dying among our soldier boys on the far-flung battle line; men long retired from active practice who are using their medical licenses in forwarding unworthy commercial enterprises; men who have abandoned all notion of reputable practice almost from the start of their professional career; fakers, quacks, irregular, illegal, immoral, unethical, untrained men, who grow rich on gullible humanity and trail in the dust and the dirt the banner of one of the great professions. To be asked to enforce a medical practice act, without having the machinery for ascertaining who is entitled to its privileges and who is ignoring its restrictions, at best is a difficult situation. The advantages of an annual registration on the payment of a nominal fee as an effective weapon for protecting the profession and for aiding in the prosecution of pretenders and offenders have been proved beyond question in connection with many professions, trades and occupations. It is surprising that the medical profession, which has needed such a bit of administrative machinery so greatly, has not availed itself of it, although it has been successfully used by others.

ADVANTAGES OF ANNUAL REGISTRATION

No greater help could be furnished the department in its administration than an annual registration of physicians. The argument for it, in brief, is this:

1. It would enable the department to keep in touch with legal practitioners. As has already been said, under present conditions the department has no definite knowledge concerning the number of medical practitioners in Illinois. When an individual has passed the required examination and has received a license to practice, he goes his way so far as the state is concerned, and possibly is never heard of again unless he is arrested for wrong doing or corresponds with the department for some special reason of his own.

2. It would be a great aid in keeping a correct roster of addresses. As it is, the American Medical Directory, published biennially, is a directory through which an attempt is made to indicate the location of every physician in the country, Illinois being included in the classification. Deaths, removals and withdrawals from active practice make this volume out of date before a new edition can be prepared. There is published annually in Chicago a volume bearing the title "Chicago Medical Directory," but this is more or less of a commercial proposition, and its lists of practitioners are sometimes defective. The state board of health, from time to time, was accustomed to prepare a list of regularly licensed practitioners, but this was confessedly faulty also. The importance of having as correct a list as possible of those who are entitled to the privileges of the Medical Practice Act needs no argument. With such a list available, department officers are able to state at once whether an individual is licensed or not.

3. It would enable the department to discover cases of individuals using the licenses of others who have died or have left the state, or from whom certificates may have been stolen or purchased. While such instances, under present arrangements, are brought to light only by accident, if there were an annual registration required, they would be quickly discovered.

4. It would enable the department better to control some of the unethical practitioners whose actions bring discredit on the profession. The occasion for the annual registration renewal would afford opportunity to the Medical Examining Committee and the officers of the department to consider whether on the whole it was desirable to permit the continuance of such an individual in the practice of his profession. There is no doubt at all that this annual review of methods pursued by a relatively small number of unethical physicians would be a powerful policing agency.

5. The annual registration fee of, say, $2, would furnish funds for the activities of the department at slight cost to the individual physician. It should be kept in mind that the larger part of the appropriation made to the department by the legislature is in the nature of a reappropriation of fees paid into the treasury through the department by members of various professions, trades and occupations. This money is used for the maintenance of the office staff, which includes the inspectors on whose shoulders falls the burden of making investigations throughout the state. The larger the amount of these fees the more effective the department can be in its administration, because better supplied with a working force. It may be worth while to note that the annual renewal fee for structural engineers and for master plumbers is $10; for architects, $5; for chiropodists, $2; for registered pharmacists, $1.50; for barbers, embalmers, horseshoers, assistant pharmacists and journeymen plumbers, $1, and for dentists, $1 paid biennially.

6. The willing payment of such a relatively small amount would provide an effective argument against the imposition of a larger annual state license fee, easily possible in these days of regulation when governments are seeking everywhere for increased opportunities for raising needed funds.

7. It is strictly in line with the best practice in other professions which, in nearly all of the states of the Union, have long been accustomed to the registration plan for the protection of their members and for the general interests of their special occupation.

8. This fee is favored at the present time by many of the leaders of the medical profession throughout the country who realize the pressing importance of thorough supervision of those who claim the privileges of the physician.

OBJECTIONS

Only two objections have been made to the proposition as it has been discussed with many prominent persons. One has already been sufficiently considered, namely, the alleged superior dignity of the medical profession when compared with others. As a disinterested layman, it is my frank opinion, for the reasons already set forth, that there is absolutely no basis, except possibly a historical one, for any such pretentions.

The other objection is one of inconvenience of having each year to send a small check in response to an official notice from the Department of Registration and Education. The one who first stated that objection to me wore on his coat lapel a jeweled emblem which indicated that probably he was a member of at least four branches of a certain fraternal order. If the methods of these bodies are those usually followed, he cheerfully pays at four different times a year a relatively small amount in the shape of dues in order to keep himself in "good standing." To any one sincerely interested in the welfare of medical practice in the state of Illinois, such an objection carries little weight.

CONCLUSION

The department attempted, during its first year of existence, to enforce the Medical Practice Act to the best of its ability. Its officers are confident that if it could have the additional machinery which would be furnished by the inclusion of an annual registration provision in the law, it would be able to render greater assistance to the profession which the county society represents. We ask the earnest aid of the members of county medical societies throughout the state in securing this desired movement. The irregular, illegal and unethical will oppose it. It is those who stand for the better things of life, who have pride in the profession they practice, who are quick to resent imputations against its honor, to whom the department must look for the cooperation which will bring to it the one bit of administrative machinery which it now lacks in order to do what the Medical Practice Act clearly intends should be done.

An Objection to Dried Milk in Infant Feeding.—The Cheshire (England) Local Medical and Panel Committee in a letter to the president of the Local Government Board objects to the Board's unqualified approval of dried milk in infant feeding as follows: "The Local Government Board leaflet, "Dried Milk for Infants," dated March, this year, states: "Experience during the last twelve or fourteen years shows that dried milk is one of the most satisfactory forms of cow's milk for use in the feeding of infants." That is a most misleading statement. The very large and carefully recorded experience of the Manchaster Children's Hospital on the relative sickness incidence in breast-fed babies, babies fed on cow's milk, and babies fed on dried milk, shows that while breast-fed babies suffer least, babies fed on dried milk have a far higher sickness rate than those fed on fresh milk. Dr. Ashby, physician to the Manchester Children's Hospital, writes on June 11, 1918: "I have no hesitation in saying that I have found cow's milk superior to any dried milk or artificial food in my work with infants and young children at Manchester and Salford."

INTESTINAL OBSTRUCTION

CONTINUED STUDIES *

H. B. EISBERG, M.D.
AND
J. W. DRAPER, M.D.
NEW YORK

Additional evidence is accumulating that death caused by intestinal obstruction is due to toxins originating in the epithelium of the duodenum and its appendages. Duodenal transplantation is, therefore, a satisfactory method for the experimental study of the cause of death in obstruction.

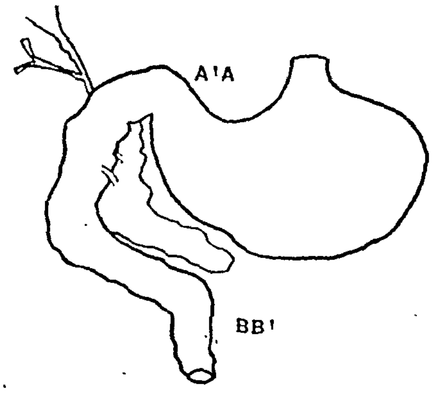

Fig. 1.—*A'A-BB'*, duodenum with its outbuds, the pancreas and liver.

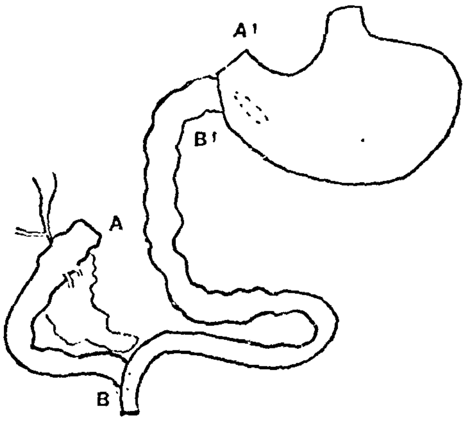

Fig. 2.—*A'*, oral occluded pylorus; *B'*, aboral jejunum anastomosed to stomach; *A*, aboral occluded pylorus; *B*, oral jejunum anastomosed to ileojejunum.

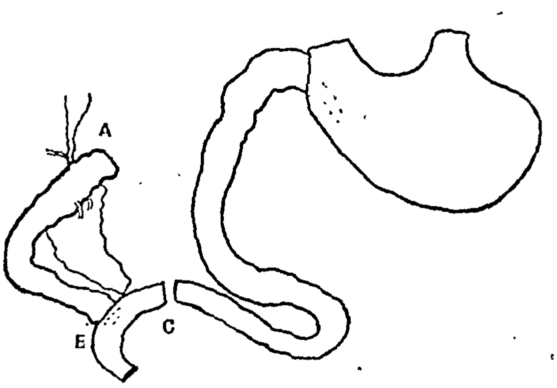

Fig. 3.—Same as Figure 2 with an obstruction.

Rogeré, and *more recently* Whipple and his associates, have laid special emphasis on a proteose from the duodenal region. Sweet and his associates have laid special stress on the pancreas. Dragstedt, Moorhead and Burcky, on the other hand, again take up the bacterial origin of this toxemia.

Our continuation of the study of this interesting problem has centered on three phases — transplantation, proteose isolation and obstruction ratio.

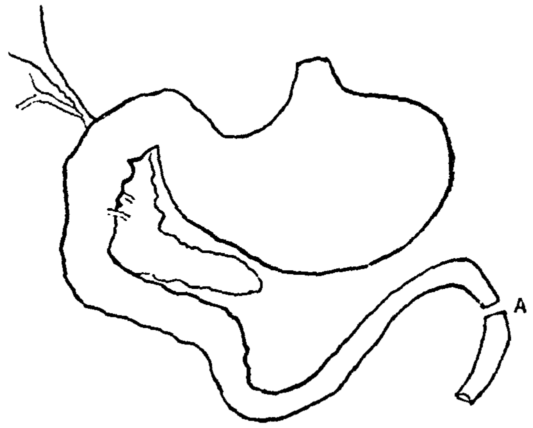

Fig. 4.—*A*, obstruction at ileojejunum corresponding to obstruction at *C*, Figure 3.

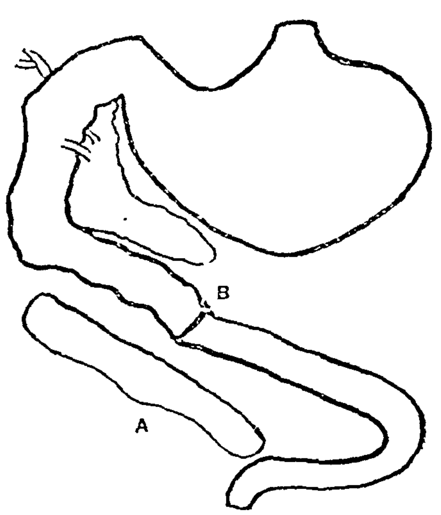

Fig. 5.—*A*, occluded loop; *B*, reconstructed alimentary canal.

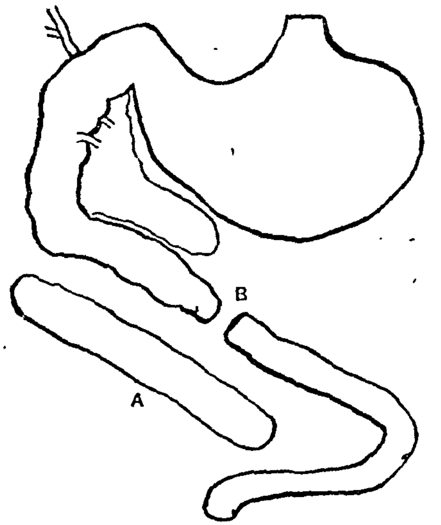

Fig. 6.—*A*, occluded loop; *B*, obstruction of alimentary canal.

DUODENAL TRANSPLANTATION

The entire duodenum with its outbuds, the pancreas and liver, are first separated from the alimentary canal (Fig. 1). The pyloric end of the segment and the stomach are occluded, the duodenum is anastomosed to the ileojejunum, and posterior gastrojejunostomy is performed (Fig. 2). This constitutes the primary operation. From two to three weeks after, obstruction by section and infolding, 35 cm. aboral to gastrojejunostomy was produced (Figs. 3 and 7). This corresponds in position to the duodenojejunal obstruction as shown in the control (Fig. 4).

The results were as follows: Dogs operated on as above lived seventeen days in *comparison* with six days in the control animals and three days longer than after obstruction in any part of the small intestine except at the sphincter. Colonic obstruction caused death in fourteen days at the ileocecal sphincter, or in twenty-eight days if at the rectum. Moreover, and of great importance, is the fact that, clinically, duodenal transplantation prevented the occurrence of classical symptoms of duodenal obstruction such as *tachycardia, tremors and spasticity*, as described by one of us in the original report, in which it was pointed out that this condition closely simulated parathyroidectomy. After transplantation, the obstructed animal remained clinically normal for from seven to twelve days after operation. There was gradual increasing emaciation and occasional vomiting. The entire picture simulated that of rectal or esophageal obstruction with complete absence of all fulminating toxic symptoms.

The conclusion is that the *duodenum*, with its embryologic outbuds, furnishes the cause of death. If the jejunum creates a toxin it is certainly of low lethal grade.

PROTEOSE ISOLATION

In reference to the proteose of Rogeré and of Whipple, we have reported that we were unable to duplicate the experiments because of faulty chemical technic. Since then we have repeated Whipple's experiments and have caused death by the injection of the residue. Curiously enough, analysis of the charts showed that when fluid was obtained from blood loops, no reconstruction of the intestine having been done (Fig. 6), the intoxication was produced. If, however, end to end anastomosis or gastro-enterostomy (Fig. 5) were used to reconstruct the intestine continuity, the symptoms were either very slight or were absent.

To explain this phenomenon we offer Sweet's suggestion—that the toxic agent was formed in the duodenum but excreted into the occluded loop. This view is strongly supported by our observations after duodenal transplantation and also by the views of Dragstedt, Moorhead and Burcky, namely, that their animals with jejunal loops lived indefinitely if no rupture occurred, whereas, those with duodenal loops all died within from twenty-four to forty-eight hours, excluding those that died from rupture. Their interpretation, that bacteria are the sole cause of death in intestinal obstruction, we cannot harmonize with certain facts. First, the duodenum is virtually bacteria free, as compared with the terminal ileum and colon, as Halsted and Cushing, as well as Brown and Blake and one of the writers, proved many years ago. Second, closed segments of the terminal ileum and of the colon, regions where bacteria abound, are not incompatible with long life.

TRUE LETHAL LINE OR POINT OF MAXIMUM OBSTRUCTIVE TOXICITY

Whatever the composition of the toxin of intestinal obstruction, which we believe to be of the same nature as the known endocrine secretions, partly because of the similarity of the symptoms after parathyroidectomy or duodenal obstruction, all observers have agreed that its most active manifestations occur following duodenal obstruction. There is a point in the second portion of the duodenum at which acute obstruction causes death more rapidly than elsewhere in the intestine. This point we have referred to as the true lethal line in distinction to the one which was described by one of us in relation to the twine triangular stitch for gastro-enterostomy and located some 20 cm. aboral to the true lethal line. Oral or aboral to this line there is a proportionate decrease of obstructive toxicity. While the exact ratio is not yet accurately worked out, one undoubtedly exists, and we have shown it roughly in Figure 8 to be approximately 1:4 in length of life, and 1:8 in length of intestine. These figures are arbitrary and may be shown by future work to be inexact; but the fact remains that there is a constant mathematical ratio that can be determined by further experiment. It may resemble the healing curve of Carrel. Lynch has suggested that there is normally some biochemical product brought down from above similar in nature to prosecretin. With this view we are in hearty accord.

SUMMARY

Duodenal transplantation definitely shows that the duodenum and its appendages, singly or collectively, produce the lethal agent which causes death in intestinal obstruction.

A proteose may be isolated under certain conditions. This will cause death if injected. Further definite corroboration, however, is necessary to prove that this test tube product is identical with the vital lethal product of acute obstruction.

A true lethal line or point of maximum obstructive toxicity exists in the second portion of the duodenum, oral and aboral to which, obstructive death occurs in a definite mathematical ratio.

The lethal agent is probably of biochemical origin similar to parathyroid or other endocrine secretions, interference with which causes death.

ABSTRACT OF DISCUSSION

Dr. Dwight Henderson Murray, Syracuse, N. Y.: A few years ago I heard a paper on this subject that gave us the information that the poisons produced in a closed loop of the intestine were many times stronger than phenol, morphin, strychnin and drugs of that kind. I should like to ask if any tests were made to determine the lethal dose of these poisons.

Dr. James J. Moorhead, Chicago: Did you occlude the duodenum with the pancreas attached?

Dr. Eisberg: It is occluded at the oral end, and the aboral end is united to the gut. A gastro-enterostomy is performed at either end; the secretions of the duodenum supposedly flow into the lower intestinal tract.

Dr. Moorhead: How long did those animals live?

Dr. Eisberg: Seventeen days; that is, after the secondary operation was produced by obstruction above this duodenal transplant; and that is about twelve days longer than the control animal by an obstruction placed at the same level with the duodenum inside. Our point is to show that the duodenum itself, and only the duodenum, with its outbuds, is the true cause of death from intestinal obstruction; and we do believe now that we have evidence it is not the duodenum alone, or the bile alone, or the pancreas alone, but the three working together, and special emphasis is laid on the fact.

Dr. James J. Moorhead, Chicago: As to the cause of death from intestinal obstruction, we are still of the opinion expressed in our recently published article, namely, that bacterial activity plus necrotic tissue, or the absorption of toxic products resulting from the action of putrefactive bacteria on necrotic tissue is the important factor. It is our intention in the near future to report results following complete extirpation of the duodenum.

Dr. Harry B. Eisberg, New York: As to the lethal dose of Whipple's proteose, we have been able to produce death within twelve hours with 150 mg. of the residue. The lethal dose, as far as the cause of death was concerned, depended, in part, on the individual animal. Some animals showed a greater immunity than others.

In reference to the origin of this toxic material, which is described by Whipple as a proteose, our evidence is as follows: It is a laboratory product obtained from occluded loops of the duodenum and jejunum. The important point is to remember the common origin of the duodenum, the liver and the pancreas. The lethal agent in true obstruction is a biochemical substance associated with the endocrine products arising from the epithelium of the duodenum and its outbuds, the liver and pancreas.

We agree with Dr. Moorhead that fat necrosis is a frequent and troublesome factor in any experimental work on the pancreas. His views regarding tissue necrosis as the cause of death in obstruction have been considered by ourselves and by others. Necrosis, except in occluded loops, plays no part in true obstructive death. If a loop is occluded with subsequent interference to its blood supply by distention, etc., and the intestinal canal is reconstructed, obviously there is no true obstruction. Death is then due to proteose intoxication arising from devitalization and autolysis of the intestine composing the loop. If not reconstructed there is a loop obstruction plus a true intestinal obstruction. This causes, in addition to the proteose, absorption of unidentified toxins oral to the point at which the loop was made. These toxins are due to endocrine disturbances of digestional epithelium.

Thus we see that there is a great difference between the death following an occluded loop with or without reconstruction of the canal and simple surgical obstruction by clamp or simple suture.

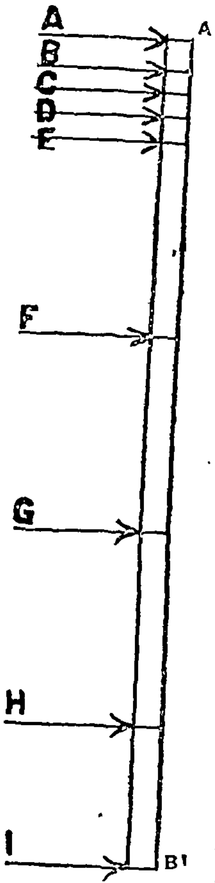

Fig. 8.—Length of life, 1:4. *A'*, seven days' esophageal obstruction, *B'*, twenty-eight days' rectal obstruction.

British Maternity and Child Welfare Act.—This act, as pointed out in a circular letter issued by Mr. Hayes Fisher, president of the local government board, enables local authorities to make such arrangements as may be sanctioned by the board for attending to the health of expectant and nursing mothers and of children under 5 not being educated in schools recognized by the board of education. As summarized in the *Medical Officer,* the local government board's grant has now been made available, among other things, for hospital treatment of children up to 5 years of age; lying-in homes; home helps; the provision of food for expectant and nursing mothers and for children under 5 years of age; crèches and day nurseries; convalescent homes; homes for children of widowed and deserted mothers, and for illegitimate children; experimental work for the health of expectant and nursing mothers and of infants and children under 5 years of age.

THE SILENT PROSTATE *

JAMES A. GARDNER, M.D.

BUFFALO

The seriousness of prostatic obstruction in old men has long been recognized by the profession. The education of the public with regard to the neglect of this condition has made rapid strides during recent years. If the insidious growth of the obstruction interferes with the bladder outlet, it causes residual urine. The onset is so very gradual that the symptoms vary. According to Kidd,[1] the onset may be divided into three clinical types. He sets these forth in such a concise form that I wish to use his classification:

1. *The Irritable Bladder Type.*—A man between 50 and 60, who develops an irritability of the bladder, finds it necessary to get up at night. This frequency increases until he notices that he is also voiding frequently during the day time. He finds that when the call for urination comes it is necessary to find a convenient place quickly. This condition increases until finally after a year or eighteen months he has complete retention.

2. *The Painful Retention Type.*—A man apparently in good health between 50 and 60 suddenly discovers that he is unable to pass his urine. After a few hours he is taken with painful cramps in the hypogastric region, and has an intense desire to pass his water, which he finds impossible, and he sends for a surgeon.

A dose of morphin and a hot bath are usually all that are required to relieve this attack. These attacks are repeated until he finally develops retention when it is necessary to catheterize. These attacks are painful because his bladder muscle is in good condition and able to undergo cramping contraction.

3. *The Painless Incontinence Type.*—This type, which I wish to emphasize in this paper, is pictured by the wasted old man whose digestive apparatus is upset, who has a continual thirst, drinking large quantities of water, and who finds it necessary to urinate every few minutes.

He is not able to control his urine, and often it dribbles away, soiling his clothes, and because of the offensive odor his presence is objectionable to other persons. Patients of this type frequently complain of backache.

When they are examined they are very much astonished to find that the cause of their trouble has been a full bladder. They felt that the bladder was empty because they were urinating every few minutes. This is the type of case in which a complete emptying of the bladder at the first catheterization may bring about very serious results.

The condition is due to complete painless atony of the bladder muscle, with retention and overflow, and the "lumbago" is caused by back pressure on the kidneys.

It has been demonstrated repeatedly that it is the shape and not the size that causes the obstruction. I have in my collection two most interesting specimens showing this condition.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Kidd, F. S.: Urinary Surgery, p. 333.

One is from a man aged 83 who had 10 ounces of residual urine, and the other from a man aged 85 who had a pint of residual urine. Although the size of the second prostate was ten times the size of the first, the smaller obstruction caused just as much trouble as the larger one. In fact, the man with the larger prostate had been more comfortable, in that his prostate as it enlarged had not at first pushed in toward the urethra.

Some of these patients progress with their residual until the frequency of urination sends them to the physician. Others may continue with broken rest, frequency and straining, till wet feet and chilled skin bring on retention, when they must be catheterized for relief. They may, however, fall into the hands of a surgeon like the one who put himself on record in a recent journal, stating that he had never seen a ruptured bladder from overdistention, nor was there any record of such a case in the hospital in which he operated. He advised that nature be allowed to take care of the condition, completely overlooking the fact that the back pressure would injure the kidneys, and that the patient would die of "Bright's disease."

DANGER OF ENLARGED PROSTATE TO KIDNEYS

Urologists have endeavored for a number of years to impress on the profession that the danger from an enlarged prostate emanates from the injury caused by the back pressure.

As I have stated before, the majority of patients do not remember when the first symptoms began. Pain is more often absent than present during the first year and a half. Consequently the patient sees no need of consulting a physician. It is during this time that irreparable damage may occur to the bladder and kidneys.

If the bladder muscle is strong, it may develop cramps, the muscle resenting the overdistention. There may be pain in one or both kidney angles from back pressure. This should not be overlooked and considered "lumbago," as it is one of the very important symptoms.

Obstructions of the lower urinary tract give rise to early destructive changes in the kidneys. The kidney pathology is not the only thing that occurs, for there is the secondary cardiovascular and metabolic disorders, which are often of sufficient prominence to mislead the physician, and cause him to overlook entirely the real source of the trouble.

In a majority of patients presenting themselves for examination, we find that a urinary infection has already taken place. This may be confined to the bladder, but frequently the kidneys also have been infected. It has long been recognized that if a patient has a mild urinary infection and recovers from it he becomes immune to a certain extent. This has frequently been demonstrated by the exceptional patient who has been catheterizing himself for a long time, and who is held up as an example in the community of a man not requiring operation.

We know that 10 per cent. of patients leading a catheter life die from a general infection within two months. These patients, because of poor drainage, unfortunately are not able to withstand the onslaught of the bacteria. Crabtree and Cabot have shown that the patient with sterile urine after a few catheterizations develops colon bacillus pyelonephritis.[2] This infection need not necessarily be a contamination caused by catheterization, but may be through the blood stream.

As has been stated, the patient who has had a mild infection and becomes immune is a better operative risk. Recognizing the fact that all patients will have more or less infection following the cystotomy, whether by the suprapubic or peritoneal route, I have felt that if adequate drainage is provided, the severity of the infection may be better controlled. The effect of infection on the kidneys is a very definite one. The patient is irritable, restless, and usually complains of great weakness. The specific gravity of the urine drops, and the amount of secretion often becomes very scant. At this stage the phthalein test shows a very small output. Under vigorous elimination, the kidneys recover their equilibrium, and the patient improves.

In the past when the single operation was performed in prostatectomy, this infection added to the shock of the removal of the large prostate often was a sufficiently deciding factor to cause death, or to cause great anxiety as to the prognosis. Following this, as the importance of the preliminary treatment was duly recognized, frequent catheterizations improved the patients and the mortality decreased. Then the indwelling catheter was used, but many patients had such sensitive urethras, and the accompanying epididymitis occurred so frequently, that, although this seemed to be an improvement on frequent catheterization, yet it was not the ideal procedure.

SUCCESS OF THE TWO-STEP OPERATION

About this time, the two-step operation was evolved. Pilcher demonstrated that patients who are poor operative risks are able to weather the strain, when operated on by this method. His arguments interested me and I have since followed out the two-step method with a series of 112 cases without a death. In the one hundred and thirteenth case, the patient died of embolus fourteen days after operation.

The patient, No. 1390, aged 52, entered the hospital, March 8, 1918, having 15 ounces of residual urine. Examination revealed no enlargement of the prostate per rectum. Cystoscopic examination showed a small medium lobe. March 9, suprapubic cystotomy was performed under procain. March 13, the phthalein test showed 40 per cent. for the first period and 20 per cent. for the second period. March 14, under general anesthesia, the medium lobe was removed. Convalesence was uneventful. The patient was sitting up in a chair on the fifth day after operation. On the fourteenth day, after being up two hours and eating his lunch, he prepared to return to bed for the afternoon rest hour. While getting into bed, he became cyanotic and died within five minutes. He had not complained of pain, and a short time before had spoken of feeling so well that day.

Three quarters of the patients presenting themselves for operation have infected bladders, or if the bladder is sterile, the presence of the drainage tube will cause an infection. Again, if there should be a severe infection of the wound, the patient can stand it much better than if he had the added burden of a prostatectomy.

I believe that the surgical principles on which the operation is based are sound, and that the infection which is bound to occur may be cared for by free drainage with little risk to the patient. Aside from giving free drainage to the urine, we incidentally prepare the operative field by having the tract walled off by granulation tissue. It is not infrequent in these cases that there is so much congestion, that following a simple cystotomy, blood is present in the urine for the following three or four days, and in two cases it became necessary to pack the bladder to control the hemorrhage. Undoubtedly these patients would have died if, in addition to the cystotomy, the prostate had been removed.

---

[2] Crabtree, E. G., and Cabot, Hugh: Colon Bacillus Pyelonephritis, The Journal A. M. A., Feb. 24, 1917, pp. 589-591.

Tumors which are large and succulent will in many instances decrease from one third to one half in size after drainage for one or two weeks, thus decreasing very materially the risk of hemorrhage following the second operation. With the two-step operation and the preparatory treatment we have not had the secondary hemorrhage which, following the single operation, has sometimes been fatal.

ETIOLOGY

Hypertrophy of the prostate is a misnomer. There have been extensive embryologic, histologic and gross studies by urologists to determine what this condition is, with a number of varying opinions. In a study made on this subject[3] based on 100 specimens we found that the enlargement was caused by an adenomatous growth. These adenomatous nodules were found in one patient as early as 38 years of age, and the others developed between the ages of 40 and 60. The growths are best demonstrated by the use of the lowest power lenses on the microscope, or a simple lens. The most convenient is the dissecting microscope. By this method, it is very easy to pick out these little nodules in a slide containing a cross section of the prostate. In the younger nodules, one is attracted by the round or oval, deeply stained nodule around which may be seen a thickening of the adjacent tissue. A little later the epithelium has proliferated and, when seen with the higher powers of the microscope, resembles the epithelium of the prostate. As the adenomatous growth enlarges, it pushes the prostatic tissue to one side, compressing it so that it has been called the prostatic capsule. As this mass grows, as has been stated in the foregoing, it is the shape, not the size, that causes the obstruction.

If the operation is performed by the suprapubic route, this mass is simply lifted out and does not interfere with the vesical sphincter, nor are the ejaculatory ducts injured. Neglect in properly interpreting various symptoms has caused mistakes in the diagnosis of prostatic obstructions. There are various conditions which may cause obstruction in a man between 55 and 60 years of age. These cases should be carefully studied to eliminate beginning of tabes, stricture of the urethra, diverticulum of the bladder, and growths, or stone of the bladder.

If a patient's reflexes are carefully tested, and a Wassermann test of the blood made, and if there is any question, tabes may be eliminated. Enlargement of the prostate is often mistaken for urethral stricture because the spasm causes an obstruction of the urethra. Diverticulum of the bladder may cause residual urine, and the symptoms of an obstructive prostate. Diverticulum is caused by an obstruction in the lower urinary tract, and often complicates the enlarged prostate. It is quite essential to make the diagnosis of diverticulum previous to operation, so that the patient may understand that this condition should be cleared up following his prostatectomy, since it is not wise to subject him to a long operation at one sitting. The cystoscope will, of course, clear up the presence of stone, tumors of the bladder, median bar or diverticulum.

Early obstruction in men between the ages of 45 and 50 causes us to think of malignancy of the prostate. It has been stated that 25 per cent. of all cases of enlarged prostates are malignant. The growth usually begins in the center and, since the capsule is dense, it is some time before it breaks through. It is therefore essential that operation should be early, if permanent relief is expected.

If a little care is given in the taking of history, an examination will easily demonstrate whether there is present a simple enlargement of the prostate or one of the other conditions obstructing the flow of urine. Diagnosis previous to operation is very essential in many of these weak old men so that the existing condition may be relieved with as little strain as possible on their reserve strength.

The patients who present themselves with clear urine free of pus, in which chemical examination shows a small amount of albumin, often mislead the physician into believing that there is a chronic nephritis. In many of these cases, following the preparatory treatment, the albumin is markedly diminished or clears up entirely, showing that it was caused by the temporary back pressure. The chemical and microscopic examination of the urine is important, but it does not demonstrate the kidney function. Though various tests for kidney functions have been advanced which are of more or less aid in deciding the quality of the surgical risk, I believe that in the phthalein test, Geraghty and Rowntree have given us the simplest and most satisfactory one.

OPERATIVE PROCEDURE

Our method is to have a functional test made when the patient first enters the hospital, and we are guided to a certain extent as to the time of performing the second operation by the improvement in this functional test. The patient who only excretes from 5 to 10 per cent. during the first seventy minutes is a poor operative risk. On the other hand, when they excrete from 40 to 50 per cent., we consider them good operative risks. This rule is not hard and fast, however, because we have operated successfully on patients who excreted but 10 per cent. during the first period of seventy minutes. The test is carried on for two periods of seventy minutes and fifty minutes respectively. The excretion is frequently slow, and the greater portion of the dye may be passed in the second period. The phthalein test is not used as the sole index to the surgical risk, but the general condition of the patient aids us in our conclusions. As the patient improves under elimination, sweat baths and bowel washes, and when the urine is scanty, by the forcing of fluids, his functional test also improves. Following the primary cystotomy, the functional test frequently makes a marked drop, and then after a day or so begins to rebound again, demonstrating the advantage of dividing the shock into two parts.

It has been our practice, the day after a patient enters the hospital to perform the primary suprapubic cystotomy under infiltration anesthesia with procain. The patient is given from one sixth to one third of a grain of pantopon (pantopium hydrochloricum) an hour before the operation. Because of the necessity of anesthetizing each layer, the primary operation occupies a longer time than if the patient was under general anesthesia. But the patient is not suffering from any shock, and we have a chance to prepare the tract for our second operation, taking care to open the bladder as high up as possible. At this time the prostate may be examined, and our cystoscopic findings checked up. A large mushroom catheter is placed in the suprapubic wound for drainage, and a purse string suture makes a tight joint. The fascia and skin are sewed up in layers. Two days after the operation, the patient is out of bed. These old men do not do well lying down. The psychologic side should be catered to, as they feel they have made progress because they are able to be up and around. The mornings are occupied with elimination treatment of baths and bowel washes, while during the afternoons the patient is up and walking. As the general condition improves, incidentally his phenolsulphonephthalein output is improved, and he is prepared for the second operation.

[3] Gardner, J. A., and Simpson, B. F.: The Relation of Multiple Adenomata to the Etiology of the Enlargement of the Prostate Gland, Surg., Gynec. and Obst., 1914, **18**, 84-89.

At the time of the second operation, a general anesthesia of ten minutes suffices to stretch up the original opening and lift out the adenomatous prostate. The Hagner bag controls what little hemorrhage there is, and a large drainage tube of the Marion type is used in the suprapubic wound. The Hagner bag and the Marion tube are removed at the end of forty-eight hours. The bottle-pump designed by Bethune is then used. The wound is kept dry by this method and heals very rapidly. Usually after a week's use, the opening is so small that the catheter attached to the pump may be removed, and the wound heals spontaneously. An indwelling catheter placed in the urethra for a few days assists the final healing. The patient sits up in bed the second day and is permitted to get out of bed the following day. It requires from three to four weeks for the average suprapubic wound to heal.

I feel that one of the very important adjuncts to the treatment of these cases is the service of a good nurse, one who has been thoroughly trained in the care of these patients. They are able to do much to help them, both mentally and physically, and I feel that I am indebted to my nurses, to a great extent, for the good results that have been attained.

MORTALITY

An investigation recently made by Thomas,[4] of the operative reports of twenty-six representative general hospitals in Pennsylvania and the neighboring states, revealed the alarming statistics of 22.5 per cent. mortality as the result of 148 prostatectomies made during the year. Compare this, if you please, with the mortality rate of 4.33 per cent. for 1,375 prostatectomies by eight of the world's foremost genito-urinary surgeons.

H. H. Young has reported one series of 128 prostatectomies without a death, and I have completed a series of 112 unselected cases without a death. This very marked difference in statistics is caused, I think, by the attention to detail given by urologists.

ABSTRACT OF DISCUSSION

Dr. Herman L. Kretschmer, Chicago: I do not like the term Dr. Gardner uses, 'the silent prostate"; it is misleading. My experience with the so-called "silent prostate" was in the clinic of Zuckerkandl at Vienna. He repeatedly showed us patients that came in after being treated by the stomach specialists because of their gastric distress and various other ailments. These were cases that would naturally fall into this group. The prostatic picture, however, was in the background. If we will spend a little more time in getting good histories and eliciting the sequence of events with regard to the symptoms mentioned by these patients, the prostatic symptoms will overshadow the immediate symptoms of which the patients complain. The term "the silent prostate" should not be reserved for cases of benign hypertrophy. That term can also be used for cases of chronic infection in the prostate when the patients have neither urinary distress nor sexual symptoms, and in which the patients suffer from a number of complaints, such as arthritis, neuritis, etc., whereas in cases of benign hypertrophy the urinary symptoms always predominate. I was glad to hear Dr. Gardner say that he is not guided by his figures with regard to functional tests between the two stages. Functional tests should be made. They help out; they should be the most important part in determining when the second operation should be done. They are one of the links in the chain of evidence. The general condition of the patient, his appetite, whether or not he gains weight, the character of the urine, and whether the infection clears up, should all be taken into account. I quite agree that we should make these functional tests but we should not rely on them absolutely. My experience has been the same as his, that after the preliminary cystotomy there is a drop in the function, and afterward the function returns almost to normal.

Dr. James B. Cross, Buffalo: I would like to emphasize the importance of each step of the two-step operation. The principal dangers of prostatectomy from the mortality standpoint are shock, relief of back pressure and hemorrhage. Both shock and hemorrhage are much reduced by reduction in congestion of the prostate after the first step. In a large adenomatous prostate, where the middle lobe sticks up in the bladder, when you go in the second time, you find that the gland is reduced one-third to two-thirds in size. This certainly goes a long way toward reducing hemorrhage. Dr. Gardner is now using the Hagner bag. It never appealed to me that putting a rubber bag under pressure at these bleeding points was really good surgery. The results have been good, however. Dr. Kretschmer spoke of going on the general appearance as much or more than on functional tests in regard to the time of the second operation. I think that is very true. In a case I had last month the man picked up very rapidly after the first operation, but his function would not get over 20 per cent. for two hours. After ten days we gave him by rectal drip 12 ounces of Fischer's solution with 10 per cent. glucose, each twenty-four hours, without any difficulty. Three days later his functional test jumped to 28 per cent. We kept this up for ten days, then performed a second operation, without any ill results.

Another big feature in the statistics of nonmortality has been the specially trained nurses. In Buffalo we use female nurses entirely who are trained in wards before they are put on private cases. In order to provide a stimulus for them to take up this work, they are entitled to $35.00 a week in place of the $28.00 which the ordinary nurses get; and in that way we have a number of girls who are exceptionally good in this work.

Dr. J. Bellinger Barney, Boston: In reference to the Hagner bag, we have used it with good success. The bag has sometimes broken after the patient has been put to bed, and the tube was broken. In each instance, the bag ceased to perform the function for which it was designed and yet no alarming hemorrhage occurred. Sometimes during the removal of the bag the handle has come off. Were it not for the fact that a strong silk ligature was attached to the tube at its junction with the bag as well as to the handle its removal would be a matter of great difficulty.

---

[4] Thomas, B. A.: The Significance of Specializing in Surgery with Reference Especially to Genito-Urinary Surgery, Pennsylvania Med. Jour., 1916, 20, 101.

As regards the introduction of the bag we find that unless the edges of the prostatic capsule are tucked down while the bag is being blown up it does not control the hemorrhage properly.

We have also had some experience with regard to the value of special nurses. Our male nurse looks after these prostates with the utmost care, and we consider that the good results we have had are due largely to this man's faithful and efficient attention to every minute detail.

We also have found that the perineal operation is of very great value, particularly in old and feeble men. I cannot understand—I do not think it has been satisfactorily explained—why it is that in perineal prostatectomies there is practically never the amount of hemorrhage that one finds in suprapubics. We have had two cases lately where there was a very profuse hemorrhage immediately after the perineal prostatectomy, and something had to be done. We have tried every means of packing around the tube with gauze, holding the bladder neck down, but without much success; so that in these two cases we have used the Hagner bag in the reverse position, simply putting it empty into the bladder, blowing it up and pulling it down against the neck of the bladder and attaching it to the leg. That immediately stopped the hemorrhage. In one case the bag was removed after eight hours, in another case after twenty-four hours. In the meantime the patient passed three ounces of urine by urethra.

Dr. Bernard Erdman, Indianapolis: In a very large experience in prostatic work with Dr. Wishard and Dr. Hamer, we have never had the misfortune to have the bag come apart in any way.

I have a bag of my own which I have used not less than ten times. I have no hesitancy in boiling it to sterilize it. We use commonly two sizes of the Hagner bag. The smaller one we use where we have a small growth, and the larger one when we have large and easily and readily enucleated growths.

The crutch which Dr. Hamer presented to the American Urological Association last April is of inestimable value. It gives all the tension you want to make, and at the same time allows you to increase that tension, and it will deflate and allow the crutch as well as the bag to remain in the bladder. In the event that you have considerable oozing coming up you can again inflate the bag, put the tube through the opening in the crutch, drag it down tightly against the surface, and stop the bleeding. Dr. Barney is right when he says that if the bags are not well brought down into the prostatic opening after the enucleation is made the liability to hemorrhage is increased.

I have heard considerable expressions of opinion here about anesthesia, spinal, and general, but very little about gas. We use gas, oxygen and ether in practically every instance. In the summer of 1906, in Vienna, I had the pleasure of seeing Dr. Zuckerhandl do between 100 and 200 major genito-urinary surgical procedures below the umbilicus, with the use of tropacocain. They were in the habit of making a spinal puncture, withdrawing about 5 c.c. of spinal fluid; they use tropacocain in 0.5 c.c. of spinal fluid, and then with a syringe allowing it to flow in very slowly by gravity, then lowering the syringe, allowing the spinal fluid to flow off into the syringe; and in that way mixing more or less of the spinal fluid with the tropacocain, allowing sufficient time before beginning the operative procedure.

Dr. Oswald S. Lowsley, New York: I have always felt that any sort of an inflated bag in the neck of the bladder was wrong in principle. We know that the bladder will contract when distended; and if we put a bag in that causes sufficient pressure to stop bleeding the sphincter will tend to contract spasmodically with the result that it will be more apt to continue the bleeding rather than stop it. It seems to me to be much the easier procedure to put in a great big tube; in the first place, to stop the bleeding at the time of the operation, which is the proper thing to do. If there is sufficient bleeding to be embarrassing, then the patient should be placed in the Trendelenburg position while yet under the anesthetic. It can then be determined within one minute whether the patient is going to bleed seriously and bleeding points clamped and tied. It seems to me much more desirable to put in a small amount of packing, which can be increased if necessity demands, rather than put in a distended rubber bag which causes this spasmodic contraction resulting in continuation of the bleeding. The matter of suction, or the matter of proper tight fitting drainage after the operation seems to be important. I believe in the suction apparatus, because it is important to keep the patient well drained and dry. If suction apparatus is used properly it will not cause additional bleeding, because we put in a big tube and inside of that put a smaller tube which does not reach to the bladder, it only causes suction within the large tube; and then we attach that to the ordinary suction apparatus. There are various methods of drainage suction devices. Dr. Byron T. Caples at Bellevue has devised a vacuum suction apparatus which works very well.

Dr. W. C. Quinby, Boston: In the control of hemorrhage following suprapubic prostatectomy I have never had to resort to the use of the Hagner bag; I have always had one available, but have never had to use it. It has always seemed to me that one of the main aims to be strived for and which should always be accomplished before putting the patient back to bed after suprapubic prostatectomy, is a sufficient control of the hemorrhage at the time of the operation. When this has been adequate there will be no qualms in regard to the patient's subsequent career with respect to hemorrhage; and therefore, as Dr. Lowsley and so many of you have advocated in the past, and still continue to advocate, I have always inspected the prostate bed very carefully and ligated any bleeding that was definite enough to need ligation. I have found that the use of a gauze tape soaked in a coagulant (kephalin) and packed for a few moments into the cavity from which the gland has been removed is really of distinct advantage. After the bladder wall is nearly sutured and just before the drainage catheter is adjusted this tape is removed. I mention this as an added means which we make use of to prevent undue bleeding.

Dr. Bernard Erdman, Indianapolis: If you are going to put anything in the bladder why put in the gauze? If the Hagner bag prevents contraction of the bladder neck, the gauze will certainly prevent it. Packing the gauze down into the wound would not offer anything at all superior to the use of the Hagner bag, and has one disadvantage in the fact that when you remove the gauze it always causes a great deal of pain to the patient because it is packed down so tight and the blood makes it stiff and hard; whereas if you use the bag you can lubricate with sterile oil or water. You can inflate the bag and if there is any bleeding after a couple of hours you can continue to tighten up on the bag. If you do use the bag, be sure that it is packed down and that the opening is well closed. Dr. Pilcher a short time ago called particular attention to the use of the bag with a catheter arrangement. The introduction of a catheter is another element of danger; and for that reason we have simply used the bag together with a tube in those instances where the patient has no severe bleeding, packing with homoplastic gauze first if severe. Then you can go home and forget all about it.

Dr. Oswald S. Lowsley, New York: The criticisms of Dr. Erdman are not well taken. In using gauze we pack the prostatic cavity, not the neck of the bladder. In using the bag you compress the neck of the bladder. I approve of the use of any styptic.

Dr. Gustav Kolischer, Chicago: As to the hemorrhage after a prostate enucleation, I am convinced that a great many of these prostatics who die after the operation under all kinds of very scientific diagnosis, simply ooze themselves slowly to death into their bladder. Their resistance is so lowered that they cannot resist the infection which occurs after a prostatectomy. Some years ago I suggested the running of a hemstitch around the edge of the prostatic cavity and then securing the bleeding points in the bottom by ligatures. That prolongs the operation very much, being a painstaking affair, and is generally not sufficient. It does not check parenchymatous oozing.

Whether you use the Hagner bag or gauze for compression there is always one objection, you have to remove the bag or whatever it may be, and then you may have a secondary hemorrhage, which is very dangerous for an old man, and hard to stop.

In discussing this sloughing around the tube we have used for draining the bladder, Dr. Schmidt pointed out the possibility that we may have to deal with idiosyncrasies against rubber. Recently I have used glass tubes, instead of rubber tubes, and it seemed to me that the sloughing around the drainage point has been reduced to some extent. You may ask how we are going to stop the hemorrhage. I do that by transplanting fat into the cavity resulting from enucleation of the prostate. You put in a tampon that is not to be removed. Part of this fat, as proved by experiment, becomes attached, and part of it will float out in drops or chunks. Of course, you have to be careful to fasten the fat into this cavity, to tie it down with one suture; otherwise the fat will slip out of position. One of my associates put fat in and did not anchor it properly; the bladder closed up, and finally a stone formed around this fat.

The introducing of a catheter after a prostatectomy presents a great danger. Whenever you introduce an instrument you may produce very intense inflammation. The checking of the hemorrhage is absolutely important, but you will often hear statements that there is no considerable hemorrhage, or that the hemorrhage is fairly well controlled, etc. That is not good surgery. We have to be sure that the patient does not bleed after closing the wound, and that he will not bleed afterward, whether it be one or two days. The patient must not bleed at all; and you must have a guarantee against subsequent hemorrhage.

Dr. L. E. Schmidt, Chicago: I want to make the same plea that Dr. Gardner has with regard to the two-step operation. There is no question in my mind at all as to its success if it is carried out the way the doctor describes, allowing a period of time to elapse which varies in different individuals. Between the first and second step I oftentimes allow anywhere from one month to two or three months to elapse; occasionally allowing the patient to go home, particularly if they come from the country, letting them take their own time practically, instructing them to return when they feel thoroughly recuperated. With some individuals who are in exceptionally good condition, possibly a week or ten days, or two weeks may be allowed; but, as a rule, a longer period of time is permitted to elapse. Of course, if you take into consideration the entire length of time of their stay in the hospital, the two-step operation is unquestionably longer.

So far as the hemorrhage is concerned, I want to say that I have lost only one patient in over three years in private practice in connection with the two-step operation, and this death occurred from embolism four weeks after the second operation. As far as hemorrhages are concerned, I am under the impression that careful work in the enucleation eliminates the necessity of using a lot of these apparatuses, packing, etc. I have been in the habit, particularly in the last few years since I have been doing the two-step operation in which the hemorrhages are as a rule far less than in the one-step operation, of eliminating as much as possible the use of these various methods of stopping hemorrhages. I have been in the habit, though not able to state positively the exact benefit derived, of using various preparations, such as serums. It has struck me that excessive hemorrhage has been far less. The hemorrhage has been practically cleared up in the course of six or eight hours in most of the cases sometimes at the end of twenty-four hours. I think, therefore, if you can avoid the unnecessary use of the bags and packing it will avoid a lot of disturbance to the patient, particularly when it comes to the removal of these bags and gauze which we know are productive of pain; and as we know also, if they remain any length of time, the reaction in old people who have cardiac troubles is of great severity.

Dr. V. D. Lespinasse, Chicago: In regard to the transplantation of fat as a hemostatic, we have found that in addition to the mechanical effect of a foreign body we have a certain amount of hemostatic ferment produced from the breaking down of the cells of the fatty tissue that aids in the coagulation of the blood. These hemorrhages from the prostatic capsule can be controlled perfectly by the use of almost any of the hemostatic powders that are on the market now, either powders or semiliquids, they are all of value. Most of them are finely ground tissue, lung, brain, etc. Some of them are serum with the water driven off in vacuo, the residue dried and powdered. The best of these hemostatic powders is made by the addition of very weak acetic acid to an extract in cold water of ground lung, which makes a brownish powder which I have used very extensively for many years, for hemorrhages of the bladder, long before these hemostatic powders came on the market at all. You can sprinkle it on gauze and then hold the gauze on the bleeding surface; the bleeding ceases almost at once and the bladder cavity is perfectly dry when you have completed the operation.

Another point about hemorrhage, if the patient is septic, he is more liable to bleed than if he is not septic. With most of the types of sepsis there is a disturbance in the mechanism of clotting of the blood, and these patients bleed much more easily and much more persistently than do perfectly normal individuals. The sepsis produces a certain amount of hemolysis so that the control of the sepsis has a very important bearing on the prevention of hemorrhage.

Finally, when everything else has been done and the bleeding still continues, fill the patient's blood vessels with blood by some of the methods of transfusion. A patient should not die simply from loss of blood. This calamity in this day and time is inexcusable. They should be filled up time after time, and then, if they keep on bleeding after one or two transfusions, try to stop the hemorrhage. The transfusion should be repeated from time to time as may be necessary. The transfusion fulfills two purposes; it replaces the lost blood and aids the patient to overcome his sepsis.

Dr. C. M. Harpster, Toledo, Ohio: Are we thoroughly convinced that the removing of the entire amount of urine from the bladder of a patient suffering from overdistention and retention suddenly, conduces to shock, and sometimes the death of the patient? I, for one, am. I have used successfully a considerable number of times, and heartily endorse the method of Lower in these cases where the patient is desperately sick, with retention and distention, and he has been severely traumatized by the attempts of the attending physician to pass a sound or catheter. I pass a large trocar just above the pubes (the intestine will not be over a distended bladder) and pass a large catheter through the trocar and fix the catheter in position with a stitch through the skin high on the catheter, or fix the catheter with the catheter retainers of Euard. By having an artery clamp on the end of the catheter, the urine can be let out at will. In some of my cases, before removing the prostate, where an acute retention has occurred, I have left the catheter in position three or four weeks. In this way I have been able to relieve the back pressure, and at the next sitting the prostate can be removed perineally or suprapubically as desired. In a number of cases I have done a perineal prostatectomy after this method of suprapubic drainage has been used for some weeks.

Dr. MacGowan: Do you cut down on the bladder?

Dr. Harpster: No; I place catheter in the bladder, through the trocar, and fix the catheter with a stitch or otherwise. No anesthetic is necessary, as a rule, although I have in several instances infiltrated with procain. It can be done in a minute. There is no shock or disturbance to the patient. I have never seen extravasation of the urine occur as is claimed by some. If properly done you will not puncture any bowel or have any extravasation of urine.

Dr. Granville MacGowan, Los Angeles: I have seen peritonitis and urinary infiltration following the use of the trocar and disapprove of it. The discussion has proved profitable in making prominent the devices for the control of hemorrhage. First, the Freyer tube; for many years I combated its usefulness, but after having employed all kinds of systems of drainage and appliances and devices for stopping hemorrhage in the past four years, I have satisfied myself that the great big tube of Freyer has every advantage to commend it, in safety for the patient and comfort for his attendant. The tube must be sufficiently large so that it gives free exit to all drainage and must not touch the bottom of the bladder or come in contact with the internal sphincter, for it will cause intermittent irritation and tenesmus which will produce the hemorrhage it is sought to avoid. Any ordinary hemorrhage after a prostatic operation will be controlled by this tube. Dr. Louis Schmidt seeks to prevent hemorrhage by commencing at the anterior angle of the gland and believes one is less likely to break into the capsular network of the veins in this way, which seems reasonable. Whenever one packs the cavity, the gauze cannot be removed without danger of secondary hemorrhage until it has loosened itself. I have had some very disagreeable experiences following removal of gauze packs from prostatic cavities. I have never had occasion to try Dr. Kolischer's idea of using fat in the prostatic cavity as a hemostatic. I cannot convince myself that it is a right surgical procedure in a hollow viscus. It is valuable about the kidney pelvis when some small blood vessel has been wounded in closing the incision and its oozing cannot be controlled by ligature.

The bag of Hagner is not an unalloyed comfort. I would not like to be without it. It has, at times, been of great service; at other times it has seemed to provoke, through causing tenesmus, the hemorrhage it is designed to prevent or to stop. If the hemorrhage is very smart and persistent in the abdominal incision, one should allow inspection of the cavity; if any blood vessels are seen spurting, they should have a ligature placed on them, or the tissues of the bladder neck basted over with a running sature of catgut, as well as possible.

Dr. James A. Gardner, Buffalo: Dr. Kolischer has answered Dr. Kretschmer's criticism of the "Silent Prostate." The patient does not recognize it and the general practitioner does recognize it but treats the patient for somthing else, and the name "silent prostate" was used for that reason. There is no question that many patients bled to death after prostatectomy without our realizing it when the continual irrigation was used. The patient was supposed to be dying of shock, when they were really dying of hemorrhage.

I fill the Hagner bag with water. Water is very much more satisfactory than air.

I like the Pilcher modification of the Hagner bag because we get the benefit of drainage through the tube that is in the urethra. The reason I have used the Hagner bag when there has been no severe hemorrhage was that I could not seem to stop the oozing, because, as Dr. Kolischer has brought out—and I agree with him—those cases which have looked all right at the time of operation, and were not bleeding much, developed a good deal of hemorrhage in from one to twelve hours.

For a number of years before I used the Hagner bag I packed the prostatic cavity with gauze. After twenty-four hours, as the urine softened the upper layers, the gauze was removed. This procedure was performed every four hours, until all the gauze came away, which usually took about twenty-four hours.

We use practically the same thing as Dr. Hamer's crutch with a slight modification; instead of using the clamp to take up the tension on the tube, we use some cord with a sailor's knot which does not slip and yet incidently does not shut down the caliber of the tube; therefore, through this tube you have drainage unless it is clogged by a clot.

I am very glad to second what Dr. Schmidt said about allowing time to elapse between the first and second operation. I think it is very important. I have had patients go three months between the first and second operation when it would have been absolutely impossible to operate on them safely when I first saw them, but having a chance to build up, they became very simple cases.

We have had a few patients every year who absolutely refused a prostatectomy, saying that they would rather die than be operated on. I inform them that they need a slight emergency operation under local anesthesia and that they can go home in about a week's time. Following the placing of the Pezzer catheter in the suprapubic wound which usually closes in a week, they are permitted to go home with instructions to use sweat baths; have the bladder washed daily and keep the bowels open. After being home for a week they return, stating that they feel very much better but that the suprapubic drainage was rather inconvenient. It is very easy at this time to persuade them to have a prostatectomy.

Dr. Harpster spoke about Dr. Lower's trocar. I was very much pleased when I got my first one. I tried it on two or three occasions but found that it seemed to irritate the patients. My main objection is that men who could use it safely can just as easily do a suprapubic cystotomy, and those who cannot perform a cystotomy will either go anterior to the bladder or behind into the intestines.

ACUTE COLON BACILLUS INFECTION OF THE URINARY TRACT *

J. DELLINGER BARNEY, M.D.
BOSTON

Much careful and fruitful study has been given the question of acute nontuberculous renal infection. The work of Brewer, Cunningham, Keyes, Jr., David, Cabot and Crabtree, and finally, that of Culver, Herrold and Phifer shines forth brilliantly and forcibly. At the same time there is no denying the fact that cases of the type mentioned go frequently unrecognized, or are wrongly diagnosed, or, by a mistake in judgment, the patients are operated on unnecessarily. The object of the present communication is to emphasize certain points in the diagnosis and treatment of these cases, in the hope that they may be recognized more readily and treated more intelligently.

My observations are based on a series of cases seen during the past year, all but one occurring in private practice in well-to-do young men.

From an etiologic standpoint we know that the colon bacillus was responsible for the lesion in each case, but the exciting factor, the exact circumstance which started the colon bacillus to assume its extraordinary activity, is still in the dark. Why should an apparently healthy person without obvious abnormality of any part of the urinary tract and with urine known, in many instances, to have been previously normal, suddenly and without demonstrable cause become thoroughly infected by the colon bacillus? Such was the situation in four of my patients, the condition of whose urine was known just before the onset of the infection. In these patients, as well as in the others, there had been no urinary disturbance of any sort, subjective or objective, recent or remote.

POSSIBLE EXCITING CAUSES

By careful examination and inquiry certain possible exciting causes were demonstrable. In the first place all gave a definite history of being unusually "run down" from mental or physical overwork. Three were students in the midst of final examinations, anxious and underweight; one was a civil engineer with a difficult job on his hands and four weeks previously the victim of an automobile accident, with severe lacerations of the leg which had become mildly septic but which were nearly healed at the time of onset of the kidney infection. There was no trauma to the body but the patient was more or less shaken, twisted and bruised. Another was a mail clerk, handling more than his share of heavy mail sacks; the fifth was an undernourished, hardworking laborer, who led a most unhygienic life; the sixth was an exceedingly busy Chicago doctor, who noted the onset of his trouble after an unusual physical effort in lifting a heavy patient. In this case, however, as well as in one of the students, the civil engineer and the laborer, a chance examination of the urine previous to the infection showed nothing abnormal.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

It has been demonstrated beyond a doubt by numerous careful observers, not only that organisms of all sorts, such as cocci, colon, typhoid, anthrax, leprosy and tubercle bacilli, may and do circulate freely in the blood stream, but also may be and often are excreted by the kidney without producing demonstrable lesions in that organ. Cabot and Crabtree,[1] in their recent exhaustive study of nontuberculous renal infections, after an examination of all the evidence, conclude:

> The array of apparently conflicting testimony has brought certain eminent observers to the conclusion that in cases where no lesion was discovered it was because a slight lesion had been overlooked. This we believe to be an entirely unwarranted conclusion. In view of the fact that insoluble substances have been shown to pass the kidneys without damage; in view of the fact that many competent observers have passed bacteria through the kidney repeatedly and then examined these kidneys after sacrifice of the animal; and in view of the fact that we are daily accepting the clinical evidence obtained by the study of patients in regard to the integrity of their kidneys, we cannot avoid the conclusion that bacteria pass the healthy kidney. That they do not do so always, or under all condtions, simply confirms the well-known fact that local conditions in the kidney and general conditions in the organism influence the occurrence or nonoccurrence of infections. While we are prepared to admit the accuracy of all the observations above quoted, they seem to us to prove conclusively that organisms circulate in the blood and pass through the kidney, in many cases without producing any lesion and in many other cases with the production of various lesions.

My own experience confirms this view. One patient whose urine was known to be normal before the onset of symptoms, and who was desperately ill as a result of his infection, made a speedy and uninterrupted recovery and has had an absolutely clear and sterile urine ever since, now nearly a year since his illness. Two others who were seen shortly after recovery had but a few leukocytes and colon bacilli in the urine, in contrast to the enormous numbers of both elements found during the height of the infection. It is obvious, therefore, that the most severe infections may go on to complete recovery without operative interference, assisted only by nature and such palliative treatment as we have to offer. While no definite statement may be made, it is possible that this may account for some of the miraculous cures of kidney infection reported after lavage of the renal pelvis with various solutions, notably the solution of aluminum acetate advocated by Koll.[2]

It is also obvious from a study of my cases and those of others that infection, once established in one or both kidneys, may continue almost indefinitely in spite of all effort to relieve it, and without any demonstrable harm to the organ or to the individual. For example, one of my patients had bilateral infection of the kidneys. Constitutional disturbance, loss of weight, anorexia and backache were marked and persistent, and the temperature was elevated for many days. Today, three years after his acute illness, the urine contains innumerable colon bacilli and pus cells. There is, however, no temperature at any time, there are no symptoms referable to kidney or bladder, and the patient has gained steadily in weight and strength. In other words, he has immunized himself to the infection and it is unlikely that, barring some general or local devitalizing factor, he will have an exacerbation of the original process. Such, at any rate, has been my experience.

NATURAL AND ARTIFICIAL IMMUNIZATION

This case has followed closely the order of events seen in patients with obstructing prostate. The residual is at first clear and uninfected. With the establishment of bladder drainage, either by suprapubic cystotomy or by an inlying catheter, infection of the bladder soon makes its appearance, closely followed by kidney infection with an accompanying rise of temperature, generally ushered in by a chill, backache, malaise, a drop in the daily amount of urine, and a decrease of renal function. In other words, we have produced more or less artificially and with malice aforethought the very condition of affairs seen in the cases the reports of which form the substance of this paper. Yet experience has shown that this renal infection is beneficial rather than otherwise, and is bound to occur sooner or later. If, however, it takes place before operation, the patient weathers the storm fairly well, immunity is established, and no further exacerbation is to be expected. On the other hand, if such an infection occurs just after, instead of before operation, it goes hard with the patient, who then has the onerous task of immunizing himself against infection while he is battling with the effects of the operation. The load is often more than he can carry and he falls by the wayside.

That there is such a thing as natural immunity to colon bacillus, I think all will agree. Artificial immunity is, however, more difficult to accomplish. Some time ago, my colleague, E. G. Crabtree, working in the laboratory of the Massachusetts General Hospital, found that the blood of a normal young adult would clump colon bacilli in a dilution of about 1:40. In patients with an infection of long standing with this organism, the immunity was much higher, sometimes 1:600. In view of this, studies in artificial immunity were undertaken with what seemed at first to be marked success. The immunity, as measured by what was believed to be accurate means, was found to increase progressively with each dose of vaccine, and many cases of obstructing prostate with uninfected urine were carried through operation and convalescence with no evidences of infection.

SYMPTOMS

My belief is that renal infection with or without obvious cause in kidney or bladder may, and often does, begin insidiously and may even go on for years without the patient's knowledge. Such is the case in the old man who presents himself with an obstructing prostate and with a well marked pyelonephritis, but from whom no history of any acute infection can be elicited. But when his infection comes on after catheterization in a previously sterile urine, it resembles in its severity and sudden onset the infection seen in the cases under consideration. The difference is that in the one case we can locate the determining cause, namely, the catheter; whereas in the other, we are forced into more or less speculation and theorizing.

[2] Koll, I. S.: Am. Jour. Urol., 1911, **7**, 417.

In the acute renal infections now under consideration, sudden and severe bladder irritability was the first symptom noted in every instance. This included frequency, urgency, and dysuria and hematuria (both generally terminal) in various combinations and degrees of severity. In this respect my experience differs with that of Culver, Herrold and Phifer[3] who found that bladder symptoms stood third in order of frequency, time of appearance, and predominance. It is notable that colon bacillus infections of the urinary tract of long standing and less severity generally produce no bladder symptoms whatever.

Symptoms referable to the kidney were noted in only four cases, appearing either just after the onset of the disturbance or not for some days later. In one there was generalized lumbar pain, in another the symptoms pointed only to the right kidney, while in two attention was called only to the left kidney. Tenderness in the costovertebral angle was noted in all these cases corresponding to the seat of pain, and in those with the most severe infection it was extreme.

In only two cases was there a chill, either at the onset of infection, or during its course, but both patients presented a severe infection, and in one, from whom a blood culture was made at the height of the chill, the colon bacillus was found. While the results of blood cultures have often been unsatisfactory, I can state from a considerable personal experience in these and other renal infections that if one follows the technic developed by Crabtree, the findings will be more satisfactory. The latter, "in a series of thirty-two cases obtained positive blood cultures in 40 per cent., a ratio larger than that ordinarily obtainable in typhoid fever, which is admitted to be a bacillemia." The secret of success lies in taking the culture at the height of the chill as in malaria, and the order of events, if studied closely, will be found to be bacillemia, bacilluria, pyelitis and pyelonephritis.

A symptom noted in one of my cases, and one to which I have not seen attention called elsewhere, was severe urethritis, with a profuse purulent discharge containing the colon bacillus in pure culture. So marked was the urethritis, dysuria and urgency that the resemblance to an acute prostatitis of gonococcal origin was very strong.

A composite history of these cases embodies many of the clinical symptoms of typhoid fever. Indeed, such was the probable diagnosis in a group of cases (not recent) from the Massachusetts General Hospital, studied by Cabot and Crabtree. These authors believe that:

> These cases simulating typhoid and due to the colon bacillus, in other words, cases of colon bacillus bacillemia, are much more common than has been generally supposed. The records of any large hospital during recent years will show a considerable number of these cases in which clinical symptoms suggest typhoid, but the diagnosis could not be confirmed and they were finally discharged cured, often with a diagnosis of paratyphoid. A correct solution can be obtained only by careful study of the blood and urine with good technic, and particularly when they are seen at an early stage of the disease.

Cystoscopic examination of the bladder yields but little information. The mucosa is in some instances velvety and deeply injected, perhaps more on one side than the other, but often there is no special change. Catheterization of the ureters, however, gives more definite data. In three of my cases the urine from each side was loaded with colon bacilli and pus, while in another colon bacilli alone were found. Subsequently, however, the urine from both kidneys showed pus as well as bacilli. It has been interesting to note that in no case has there been any appreciable decrease of renal function as shown by the phenolsulphonephthalein test, either as regards time of appearance or total output. In this respect, my observations in these cases differ from those in cases of obstructing prostate, wherein after the onset of renal infection and pyelonephritis a drop in function is not uncommon. Pathologic evidence would indicate that this is due to an "acute cloudy swelling of the kidney, probably involving chiefly the tubular portion. That this process is short-lived and goes on rapidly to practically complete recovery is suggested by the return of kidney function and conclusively proved by the appearance of the kidney postmortem."[1] Clinical evidence is sufficiently abundant to bear out this conclusion, and it may be argued that in my own cases the observations were made either before any pathologic changes had occurred in the kidney or after they had cleared up.

SEARCH FOR FOCUS OF INFECTION

A careful search of each patient failed to reveal any focus of infection, past or present, which might account for the onset of the renal condition. It has already been noted that all patients were more or less below par, and one in addition had had an injury which might have indirectly induced his illness. One young man had an extensive pyorrhea alveolaris, another had been told a year or two before that his tonsils were inflamed and should be removed. The roentgen-ray examination was negative in all, in that no shadow which could be properly interpreted as a stone could be found, while in one case a painful and tender left kidney was found considerably enlarged, an observation already made by palpation of that organ. In other words, one can say no more than that the infection came, as it were, "out of a clear sky," arising undoubtedly from a definite focus but undiscovered, perhaps undiscoverable, by the diagnostic methods employed, and finding fertile soil in an organ devitalized by one cause or another.

While it would appear from the previous history and roentgen-ray examination of my cases that renal calculus was not a factor, this cannot be positively excluded. Furthermore, who can deny that renal retention, unilateral or bilateral, produced by ptosis, simple or complicated by an aberrant vessel or other band, did not encourage the prolonged residence of organisms which otherwise would be transient? Doubtless, further and more exhaustive study of these cases would have settled the question, but it would be poor judgment to undertake any prolonged examination, especially one involving, as it would, pyelography and distention of an acutely inflamed renal pelvis. In those instances in which complete recovery has taken place, or seems likely to occur, such an examination would appear to be superfluous. One can explain the phenomena by concluding that the infecting organism, arising from a definite focus, demonstrable or otherwise, overwhelmed by its numbers and high virulence first the kidney, or kidneys, and then the patient. On the other hand, when the renal infection persists for any considerable time after its acuteness has subsided, every effort should be made to determine the exact status of the renal pelvis, for it is in these cases that some interference will be found with the outflow of urine from the organ. While it does not, however, always follow that the correction of such an abnormality will wipe out the infection, it is my belief, and experience, that acute exacerbations of the infection are extremely unlikely.

---

[3] Culver, H., Herrold, R. D., and Phifer, F. M.: Renal Infections, The Journal A. M. A., May 18, 1918, p. 1444.

TREATMENT

When it comes to treatment the judgment of the surgeon may be sorely taxed and only a considerable experience, exact diagnosis, and regard for the pathology of renal infections will point the way. Having once established a diagnosis of colon bacillus infection of one or both kidneys, one is greatly aided in his decision by remembering the statement of Cabot and Crabtree that "the colon bacillus rarely produces suppurative lesions of the kidney in man, while in animals it may readily do so; and this has given rise to the quite erroneous assertion that the colon bacillus commonly, or even regularly, produces abscesses of the kidney." On the other hand it must not be forgotten, as pointed out by these authors, that "it is not rare to find kidneys showing the evidences of at least three infections differing in point of time and often in the nature of the organism involved." Given a case with history and physical examination similar to those described, "watchful waiting," tempered by judgment, and this in turn founded on experience, may be safely employed. Inasmuch as pathology has shown that the colon bacillus affects chiefly "those portions of the kidney relatively accessible to formaldehyd-containing drugs," the latter must be worked judiciously and vigorously. I consider that hexamethylenamin given in 7½, or even 10 grain doses every four hours, together with 10 grains of the acid (monobasic) sodium phosphate, and the administration by mouth or rectum of large amounts of water or of saline solution subpectorally, is a most efficient combination. Free catharsis, if not already produced by the acid sodium phosphate (which it generally is) should be accomplished. Otherwise drugs are of little value except as indicated for pain or sleeplessness. Absolute rest in bed, with hot fomentations to the lumbar region, is a sine qua non. Should a definite cause of infection, such as renal stone, be found, it should be properly treated, but in its absence palliation along the lines indicated is alone sufficient. While in a thoroughly septic patient, with temperature, chills, nausea and vomiting, profuse sweating, and a painful, tender and enlarged kidney, the temptation to operate is strong, the recollection of the pathology, the knowledge that in more than 50 per cent. of the cases the infection is bilateral, and the experience which has seen patients in other equally bad cases recover, will perhaps stay the hand that is eager to grasp the knife.

ABSTRACT OF DISCUSSION

Dr. H. L. Kretschmer, Chicago: One point that always interests us most is the route by which the colon bacillus gets to the kidney. People in Boston are very firmly convinced that the colon bacillus gets there through the blood stream. Perhaps they see more acute cases than we do. Some of the bacilli doubtless reach the kidney through the blood stream. I believe, however, that there are other routes of infection. Francke has been able to demonstrate what appears to be a direct lymphatic connection between the large colon and the capsule of the kidney. The work of the Japanese seems to point to the fact that there is a direct lymphatic connection between the lymphatics that run over the fatty capsule and the lymphatics within the kidney. If this is true, it is very easy to see how these organisms may travel through the lymph system from the large intestine to the kidney.

Asch has been able to produce bacteriuria in dogs by feeding them opium so that the bowels were locked up from seven to ten days. Without treatment of any sort, except to open up the bowels, the bacteriuria promptly disappeared; so that the lesions of the intestinal tract may be a predisposing factor in the production of renal infection by the colon bacillus. Many of these patients have a history of colitis. Many cases occur in the children's hospitals during the summer time, when gastro-intestinal disturbances are common in children. Some of our cases have had disturbances of the colon, and treat them as we would, we have been unable to make any progress until the colon conditions were corrected.

Not only lesions of the colon but lesions of other organs should always be studied. In The Journal of the American Medical Association, June 24, 1916, F. W. Goarde and I reported several instances in which infections in the prostate and seminal vesicles were not treated and the patients had relapse of their renal infection, and we came to the conclusion that they relapsed because of the presence of infection in the prostate and vesicles. In another of our kidney infections which was not due to colon bacillus, we found *Streptococcus viridans* in the blood, and in the urine from both sides and in some abscessed teeth; so that this problem is not a local urinary problem. In some of these cases we found associated lesions in the pelvic organs, and we always aim to correct these.

We accept as cured only cases in which we have been able to render the urine sterile and free of pus. We have not relied on the ordinary routine urinary examination, but insisted on obtaining sterile cultures.

Dr. Granville MacGowan, Los Angeles: I think that Dr. Kretschmer struck the real keynote when he said that both colon infection and bacteriuria are not a local but a general problem, and unless you fully admit the hopelessness of the expectation of creating a cure in so many cases, what Dr. Schmidt has so frankly said must be conceded. Yet, at the same time, that does not excuse us as physicians from using every measure we can employ and every power we possess to discover the reason or cause for the presence of these bacteria in the urine. Oftentimes, the presence of bacteria in the urine does not mean that the person is in bad health; it does not necessarily indicate that he is in a definitely diseased condition that comes home to him in the shape of particular symptoms. In every case bacteriuria is the sign and symptom of a diseased condition, and is accompanied by prostatitis in males and cystitis in females, and there is no longer true bacteriuria, but an inflammatory condition of the mucosa of the urinary tract. My observation has been that these cases of colon bacillus bacteriuria and colon bacillus infection of the urinary tract, when persistent, are invariably due to colon stasis. This chronic stasis constantly produces a constant supply of bacilli in the circulation and by lymphatic connections they get into the capsule of the kidney and from there into the cortex, down to the tubular portion, creating eventually an infection of the kidney pelvis on their way out. If there is any invasion either in the ureters or in the neck of the bladder, or in the urethra, we will in all likelihood not only have colon bacillus infection and bacteriuria but we will also have pyelitis and eventually have true cystitis.

Dr. Oswald S. Lowsley, New York: Colon bacillus infections of the kidneys and ureters are the bugbear we have to face. I quite agree with the speakers that the removal of bacteriuria is very difficult, and practically impossible. Such people should be subjected to just as thorough an examination as it is possible to give by means of the roentgen ray to determine whether there are foci in the sinuses or bony structures in the prostate. The treatment is a very interesting and delicate matter. In the height of the acute exacerbations it is unwise to give them acid sodium phosphate and hexamethylenamin, but I do think that kidney pelvic drainage is important, if the temperature remains elevated. If the patient has repeated chills and there are symptoms of distention of the kidney pelvis, put in a catheter and allow the material to drain from the pelvis. My reason for saying that it is unwise to give the above mentioned drugs in acute exacerbations is that it will produce more edema of the mucous membranes than already exists, and will tend to increase the blockage of the canal. When the catheter is in place, however, and carefully watched by a competent person and kept open, great relief may follow and the patient's temperature will generally drop very promptly and relief from that particular attack will occur. In chronic cases renal pelvis lavage is very important; but it seems to me a wise procedure not to wash out more than one kidney pelvis at a time, because the reaction after treatment is sometimes very severe, and if both kidneys are subjected to this it introduces a new complication.

Dr. Bransford Lewis, St. Louis: I would not like to have the pessimistic tone prevail as expressed by Dr. Schmidt, although I have encountered cases of bacteriuria that I have been unable to overcome. Still, I would not like to have his expression applied to all the cases that you cannot do much for them. For some you can; for some you cannot.

Success in many of these cases depends on whether or not ou detect the focus of infection.

Dr. C. W. Bethune, Buffalo: I have been very much impressed with the history of colon infection, especially in a woman whose case was thought to be trouble from overdistention of the bladder. She was in the hospital with a fractured leg. She had some unpleasant experience with the night nurse and she would not call her during twelve hours of service. After that she had a severe colon infection from which she died. I want to ask Dr. Barney if he ever used ammonium salicylate instead of hexamethylenamin? I believe Wright was the man who first suggested its use.

Dr. J. Dellinger Barney, Boston: My object was to call attention to the fact that these cases of acute colon infection of the kidneys call for the greatest discretion and the highest exercise of surgical judgment. By watching them with expert care they can generally be cured without a cutting operation. I recently saw two patients who had been under the care of other surgeons and had been operated on under the belief that there was acute suppuration of the kidney. No such suppuration was found, and the patients were made distinctly worse. I agree with Dr. Kretschmer that this is not a local affair, but that we must look elsewhere than in the kidney for the primary focus.

As to the method of examination of the urine. The culture is not of very much value, because by the time it is made, some extraneous or secondary organism may be more virile than the real offender and overshadow it. The important organism can best be found by immediately staining a specimen of the sediment of the catheterized urine. We have had but little luck—in fact, none, with the use of vaccines, particularly in these acute cases, although vaccines have been of apparent value in some of the chronic cases. We have been accused of ascribing all these infections to the blood stream. Perhaps we have become enthusiastic because of our success in finding organisms in the blood, thanks to Dr. E. G. Crabtree's very efficient work. They are found there in a very large number of instances. We do not think well of irrigation of the pelvis, particularly in the acute cases. We do find the passage of a catheter is a beneficial application, as it may straighten out a kink or remove an obstruction. We do not believe that hexamethylenamin is an irritant to the kidney, although it does produce bladder irritation in certain instances.

Dr. Louis E. Schmidt, Chicago: I find myself perfectly clear in regard to the connection between the lymphatics, the colon, and the kidney. I stated that that was unquestionably a source of a large number of infections. So far as the colon bacilluria is concerned, it is probably due to stasis or some other condition by which there is a direct connection between the bowels and the colon and then probably reaching the kidney. I know of instances where patients have been operated on for chronic appendicitis, where there have been adhesions and where certain types of bacteriuria have been cleared up. In these cases, however, there has always been an inflammatory exudate, either in the pelvis of the kidney, or in the ureter, in connection with the inflammatory mass. Following these operations in many cases some of the bacteriuria has persisted. In these cases there is, however, as a rule, always pus in the urine and red corpuscles. This is not a distinct case of bacteriuria; it is rather a colon bacillus infection. I have seen numerous cases of this type that belong to this group in which adhesions are present and the symptoms too indefinite to justify operation. I know of two cases in which operation has been performed, both patients being women, in which the bacteriuria has not been improved and the condition still persists. In these cases there have been bands and adhesions, not as in appendicitis where there is an acute inflammatory or subacute inflammatory condition. In these cases I have frequently catheterized and obtained perfectly clear urine from the upper urinary tract and at the same time have found that the urine obtained from that side would be loaded with bacteria and red blood corpuscles.

Dr. Lowsley suggested that many of these cases have reacted to lavage. If there is any trouble in these cases outside of the urinary tract, I really cannot see what you can do with lavage. I did state in my paper that washings of the pelvis might give some relief, but I do not believe that I have ever seen a cure, whether the catheter was allowed to remain in for a long time or not.

In one of my papers I stated positively that all complications that one might suspect as being the source of infection must be treated. To overlook that fact would be the height of foolishness. I did make the statement that from local treatment only of the bacteriuria you can expect results.

So far as Dr. Lewis' criticisms are concerned, if the cases I have referred to are treated in the various ways mentioned, when you cannot find any local or general condition to account for the bacteriuria, I do not see how operative interference with some outside organ can avail, where there is absolutely positive belief of any direct connection. In all these cases local treatment is of no avail, and that is what I wish to refer to particularly.

So far as Dr. Barney is concerned, I agree fully with him as to the statements of his cases. We are all familiar with cases of colon bacillus infections. I will venture to say that the vast majority of colon bacillus infections of the kidney will clear up and are certainly not surgical cases by any means. An occasional case might be met, but very rarely, however. I agree again that where there is pus, after the onset or after this period of exacerbation, where there are a lot of bacteria present, if the urine clears up, these cases are cured, or at least there is no further recurrence in a large number of them; but these cases do not belong to the type I mentioned. There is no question at all that this condition is not to be considered as being solely local.

Report on Prevention of Blindness.—The second annual report of the Illinois Society for the Prevention of Blindness covering the year ending with October, 1917, says that in the state of Illinois there are between 2,000 and 3,000 needlessly blind persons. The organized efforts of the society were begun in 1916 when permanent offices were opened in Chicago with a full-time secretary, Miss Carolyn C. Van Blarcom, who was called by the Red Cross early in 1917 to organize and carry on work in connection with that organization in the East. Miss Dorothy L. Blatchford was then appointed secretary. Twenty-two violations of the law requiring the reporting of infants' sore eyes were prosecuted, follow-up work in ophthalmia neonatorum cases reported by physicians and midwives was done, social service work was started by Miss Blatchford in the Central Free Dispensary, a bill against the improper use of wood alcohol was drawn and promoted in the legislature by Miss Van Blarcom.

HISTOLOGY AND PATHOLOGY OF THE SUPERSTRUCTURES OF THE LID IN TRACHOMA

AND TREATMENT *

E. H. CARY, M.D.
DALLAS, TEXAS

For thirteen years I have operated for the cure of trachoma in its various stages, with distinct advantage to the patient. I had observed for a long time that in the operations made for entropion, the corneal conditions were always made better; and it seemed to me that the modification of this proceeding might be useful in the correction of corneal irritation, even before entropion should appear as one of the end-results of trachoma. As there was little of a definite nature written regarding the pathology of trachoma beyond that which takes place in the conjunctiva, it offered a field for investigation and explanation, thus placing this operation on the lid on a sound scientific basis. The presentation of this subject has been delayed by me for many years, although I am on record[1] as having discussed the value of my repair operation.

I have operated in more than 500 cases, ranging from the most extreme type, that so-called melancholy condition, xerophthalmia, to those of the early second stage, in which pannus was just making itself manifest. I have reached the point at which I can say to the patient, "I will cure you in from three to six weeks," as the case may be; and in few instances has there been a return of symptoms. One of the patients, an Indian, whose right eye gave him further trouble, returned and I found a calcareous mass which, under local anesthesia, I removed and all his trouble was abated. The eyes of another young man who continued to have symptoms after my operation, did not clear up as they should, but he was cured when a canthotomy in each side was performed. There were a few cases in which the cornea would become irritated, the pannus would increase, and one or two superficial ulcerations would appear, accompanied by photophobia and lacrimation and, in truth, many of the symptoms that might be observed before operation. In such cases we shall find a soggy middle turbinal and a sagging membrane over the septum near the middle turbinal, with more or less contact between the two parts. While it is conceivable that this condition of the nose may be brought about through infection of a similar nature, it is more likely that the eye condition simply occurs in a person who has a pathologic condition of the nose, often without being conscious of any nasal symptoms. This nasal condition becomes exaggerated from the chronic inflammation of the eye, with its attendant lacrimation, etc. The removal of the middle turbinal and the cauterization of the mucous membrane which is sagging from the septum will immediately cure the eye symptoms without further eye treatment. The result may be obtained with the cautery alone, without a turbinectomy, but it is not likely to be obtained with the latter when cautery is not used to pin the mucous membrane of the septum. In other words, in the few cases in which the repair operation has been of limited value, there is a distinct reason traceable to a definite cause, which, when removed, results in the abatement of all symptoms. Usually we shall find only one eye affected, but I have seen cases in which both eyes were involved, relieved by the same nasal procedure. The conjunctiva and cornea change completely after the cauterization. The explanation of this I have attempted in another paper.

The histologic condition of the lid will indicate the kind of disease necessary to bring about the crimping of the tarsus, as well as the other changes in and around the tarsus which cause all of the disagreeable trachoma symptoms.

A quick survey of the histologic conditions of the lid from within will show the conjunctiva attached to a fibrous tarsus, in contradistinction to a cartilaginous tarsus often mentioned in the literature. Embedded in the fibrous tarsus, we have meibomian glands, which are sometimes of much importance in the pathology. Lying on the tarsus, close to the hair follicles, and spreading backward from its marginal attachment, the orbitotarsal fascia, or the palpebral fascia, as it is sometimes called, may be traced into the levator muscle. This muscle, attached to the tarsus, is split into many fibrillae, with much aerolar tissue surrounding the muscular ends. Above the orbitotarsal fascia and between it and the skin, is the orbicularis muscle, which is composed of voluntary and involuntary portions. The involuntary part, which is near the margin of the lid, keeps the eye closed when the patient is asleep. Of course, there are numerous glands and other organs of interest in the conjunctiva, as well as numerous glands and hair follicles in the margin of the lid. It is not necessary for my purpose to go into such details as a description of these structures would require. The lid is adapted to the eyeball, naturally curved. What happens to make this lid crimp and bring about the pathologic condition which, if continued, finally destroys the function of sight, is the important point I desire to emphasize.

The operative procedure cannot be successfully carried out without a clear understanding of the pathologic changes which are in process of development. If the ophthalmologist can understand this phase of it, then his repair operation will be directed to the pathologic phenomena presented. My procedure contemplates looking in on the pathologic conditions. I will present the accepted pathologic view of the early changes that take place in the conjunctiva. There are three distinct features characterizing trachoma: granulation, papillary hypertrophy, and the formation of connective tissue. By a large number of authors the disease is divided into two classes, papillary and granular.

STAGES OF TRACHOMA

In the trachoma occurring in Egypt, Callan uses a classification of four stages, depending on the comparative prominence of one of the foregoing essential features. In any classification of this disease, it must be borne in mind that the pathologic changes are so varied that it is practically impossible to have any distinct and definite classification. I see no reason why Callan's classification cannot be used in connection with trachoma in any country, so I am going to adopt this classification to a certain extent. It seems essential that I should include the pathologic conditions familiar to physicians.

Trachoma is a condition of the conjunctiva or mucous membrane of the eyelids resulting in the for-

[1] Cary, E. H.: Proc. Texas State Med. Soc., 1907.

mation of so-called trachoma granules, with or without papillary hypertrophy. In favorable cases, these granules disappear and are replaced by fibrous connective tissue. The essential and primary change in trachoma occurs in the adenoid or lymphoid tissue present in the conjunctiva; the other changes are secondary to the change in the lymphoid tissue.

In the first stage of trachoma, one will find varying numbers of small grayish or grayish-yellow islands or granules on the conjunctiva of the tarsus and of the superior culdesac, especially at the two extremities of the tarsus. These islands or granules are semitransparent, almost avascular, with small blood vessels converging toward them. The granules have an appearance somewhat similar to sago grains. This comprises the first stage of trachoma, according to Callan's classification, and may pass into the second stage or, in favorable cases or cases that have been treated, into the third or fourth stage. In the second stage one of two conditions will prevail: predominance either of granules or of the papillae.

Probably more cases of trachoma come under the observation of the physician during the second stage than during any other; hence the usual division into the granular and the papillary forms. In the granular type of the second stage, the granules are found all over the tarsi and in the upper fornix. As usually seen, the granules are from 1 to 2 mm. in diameter. They are the result of an enlargement of the adenoid nodules or lymphoid follicles usually present in the conjunctiva. This enlargement is due to hyperplasia of the lymphoid elements, that is, the lymphoid cells. Such a granule shows a vascular capsule of connective tissue surrounding a mass of cells, the more central of which are large lymphoid cells with granular nuclei, frequently containing the "cell inclusions," which were at one time considered the probable cause of trachoma. In the peripheral portion of the granules are smaller lymphoid cells, and running through the granules are strands of connective tissue. Along with the formation of the granules there is more or less hyperplasia of the adenoid tissue between the granules, with more or less lymphocytic infiltration. In some cases this change may be so marked that large tumor-like masses are formed, or so diffuse a change may take place that the tissue may assume a peculiarly glossy, gelatinous appearance. That the granules may break down, leaving ulcerations, seems questionable in the minds of many. In the other, or papillary type, in the second stage, occurs the hypertrophy of pseudopapillae. These papillae appear as red raspberry-like elevations which mask, to a greater or less extent, the typical gelatinous granules. This papillary form is most marked on the upper tarsus.

In the third stage, the formation of fibrous tissue and cicatrization is very evident. The first appearance of such cicatrization is in the form of gray or white lines, or striae, running in all directions throughout the hypertrophied conjunctiva. As the condition persists, these lines or striae become broader and more numerous. The extent of the cicatrization will depend on the extent of the primary change in the lymphoid tissue. The first part of the conjunctiva involved in trachoma is just beneath the epithelium, but the lymphocytic infiltration with the later fibrosis may involve the tarsus. The fibrosis with cicatrization may be diffuse or may occur in patches, and in some cases may have stellate arrangement.

In the fourth stage, there is a smooth conjunctiva seamed by white lines of connective tissue. Practically complete cicatrization has taken place, or in other words, the trachoma is cured, and here ends the pathologic study.

TREATMENT OF TRACHOMA

As we all know, the expression operation is frequently of value, and cures many of the cases seen early, or in other words, whenever pathologic conditions are limited to the conjunctiva, and structural changes have not taken place above it. When we reach the stage at which the case presents a pannus along with any other corneal disturbance, we may be confident that we already have pathologic changes in the tarsus, that is, in the orbitotarsal fascia, orbicularis muscle, and other structures of the lid, which make it a source of mechanical irritation to the cornea.

It has been difficult for me to determine what is the most active cause of the crimping, which we see while operating and after taking away the orbicularis muscle. I have observed in all instances a more or less marked tendency on the part of the spreading tendon of the levator with its thickened aponeurosis to roll on itself, so to speak, and to lessen the amount of tarsus in evidence after the removal of the orbicularis muscle. This we see when the tarsus is not thickened, and the crimping of the tarsus disappears as we rid it of the fibrous bands, and push back the rolled-up and adherent portion of the levator muscle. When this is done, the tarsus flattens out. This is the pathologic condition we may demonstrate, and when it is corrected, the apparent crimping of the tarsus is removed. Evidently, fibrous bands produce this rolling-up of the fibrillae of the tendon of the levator, which shortens the normal distance between the margin of the lid and the tendon. That portion of the orbicularis muscle called the palpebral portion, which has remained in a state of spasmodic contraction, is probably due to an involuntary effort of the muscle of the lid to protect the cornea.

The action of this involuntary muscle in contracting is to keep the lid closed in sleep and possibly to lift some of the weight of the lid off the globe. No doubt, the early changes in the conjunctiva have a tendency to crimp the tarsus. Then as a result of the extension of the inflammation into the loose connective tissue between the tarsus and the palpebral portion of the orbicularis muscle, there is an increase of the fibrous connective tissue. In this portion of the lid there is closer union of the muscles with the tarsus. Also, the fibrosis extends in between the fibers of the muscle, causing a shortening of the muscle, which, together with a firmer union with the tarsus, accentuates the already present crimping of the tarsus. Thus a vicious circle is established, with reflex irritation producing spasmodic contraction of the muscle, this spasm being relieved when the corneal irritation is subdued and returning as so-called exacerbations whenever the cornea becomes involved, either through something that irritates the cornea from the outside, or through any lighting up of the pathologic condition that remains in the lid. By observing the picture of the lid, we may readily see how the pathologic condition of the lid will vary in different individuals. In some, the meibomian glands become blocked, increasing localized areas of the tarsal thickening. In some cases there are calcareous deposits and changes too numerous to mention, all of which are under the observation of the surgeon when he follows the operative procedure to be outlined in the care of such cases. No doubt the ciliary part of the palpebral portion of the orbicularis muscle has more or less tendency to produce trichiasis. Splitting the margin of the lid is necessary in some cases to overcome in a more rational way the crimping and particularly the torsion of the cilia. It should be understood that tarsal resection of any degree is a kind of repair of the pathologic changes resulting more in one than in another, due to the fibrosis in the parts above, and to the changes in the tarsus and conjunctiva beneath. With a removal of a section of the tarsus, less tarsal surface is offered for muscular attachment, and this compensates for the loss of muscular tissue that is removed, and directly tends to overexaggerate in the opposite direction the previously crimped tarsus, which had forced a sulcus or sulci beneath the lid. In a broad sense, my repair operation is an adaptation of methods previously used for entropion, with the distinct difference that there is a pathologic condition to correct, which requires the removal of muscular and fibrous tissue, the breaking up of fibrous bands, and the pushing back of the levator tendon, with the probable flattening of the tarsus. All this is done with the understanding that conditions may or may not require splitting the margin of the lid. This is to be determined during the operation, and based on the operator's judgment of his control of the position of the cilia, the skin surface to be stitched. The upper portion of the skin may be removed or not, as he feels the need of pinning the skin surface to the upper portion of the tarsus. This constitutes the fundamental procedure in tarsal repair. Of course, the expression of all granules is the first thing to be done before the lid operation is begun, as heretofore described.

I must not close without impressing the reader with some points connected with the after-treatment of the lids. It is not unusual for the cornea to appear very much irritated, and the eye to look as if the inflammation were exaggerated within a few days of the operation. This sometimes is the result of the use of petrolatum ointment of mercuric chlorid, which seems to irritate some subjects; again the cause is not perfectly clear, except that the operation was performed in a dirty field, and the use of a bandage to control the swelling may tend to block drainage sufficiently to bring about superficial infection. This reaction should not discourage the surgeon; all that is necessary is to treat the lids in the way which would have been followed without the operation, and all the symptoms will rapidly clear up. In a week or ten days the eyelids will be in much better shape, to be followed later with perfect results, and the cure will be brought about in a period of time covering from two to three or four weeks. I naturally take it for granted that every man will be wise enough to treat the symptoms as presented, and if so, success will surely follow in all cases in which this operative procedure is used.

ABSTRACT OF DISCUSSION

Capt. Vard H. Hulen, San Francisco: It seems to me that Dr. Cary's operation is for the cure of the after-effects of trachoma rather than for the cure of the trachoma itself. Evidently Dr. Cary does this operation when there is entropion, because he says that in certain cases he splits the margin of the lid, and that makes practically the old Snelling operation for entropion.

Dr. E. H. Dewey, Des Moines, Iowa: I was with the Indian Service for six years, doing trachoma work. When we get an old case tarsal excision is one of the best operations to cure trachoma. I usually do it under local anesthesia, and rarely have to put in a stitch when I close the wound.

Dr. Arthur E. Prince, Springfield, Ill.: I have on a number of occasions done this operation about as described. I have obtained good results, but I have reserved the operation as a sort of last resort. I do not advocate the operation as a regular procedure. I have been much interested during the past three years in the application of carbon dioxid ice. I evert the lid so as to expose the retrotarsal fold, and make a rather light application, about two or three seconds, until the lid turns white. I freeze both lids. There is some virtue in it; I cannot tell you yet how much. I would recommend that if you have a case of trachoma that is not getting along well, freeze the conjunctiva lightly, repeat in a month and again in another month. I habitually freeze these small tendinous pterygiums with carbon dioxid ice. In all probability it obliterates the old capillary circulation, because immediately after the freezing a better condition of the conjunctiva and very much better vision is noted.

Dr. Edward H. Cary, Dallas, Texas: This operation is useful in all cases of trachoma after the first stage. It is good enough for all of the pathologic changes which take place from the time enough pathology is present to produce pannus and small ulcerations. In the first stage of trachoma you would not think of using this procedure. The question of resecting the tarsus is left for the last stage, and is not to be thought of in connection with these intervening conditions, which you can treat with a simpler or a better method of operation than this, leaving the lid absolutely normal, so that there is no evidence after a few weeks of having operated at all.

RELATIVE DIGESTIBILITY OF MAIZE OIL (CORN OIL), COTTONSEED OIL AND LARD*

ELBERT W. ROCKWOOD, M.D.
AND
P. B. SIVICKES
IOWA CITY, IOWA

At a time when the value and necessity of fats in foods are recognized as never before, the determination of the digestibility of those from new or little used, although abundant, sources is both interesting and important. Of as great interest is the comparison of their utilization with that of the fats for which they can be substituted. In this country a potentially rich source of edible oil is the germ of maize or Indian corn, which is separated from the rest of the kernel in the starch-making process.

Maize oil, or corn oil, has within the last few years been put on the market in increasing quantities. It is sometimes sold under these names, sometimes under trade names[1] that do not clearly indicate its source. The results of experiments here reported show the digestibility by dogs of corn oil compared with that of lard and cottonseed oil, for which it is chiefly substituted. It is probable that the digestibility by man would not differ much from these figures.

The dogs represented three different types. One was normal in development and vigor, a second was in a subnormal condition, and the third was excessively fat. All were adult females. As their weight did not differ materially, the same ration was used for all. It consisted of 40 gm. of cracker meal, 10 gm. of bone ash and 155 gm. of chopped lean beef, freed from visible fat as much as possible. In a fore period, no fat was given and the ether-soluble material was determined in the feces and regarded as the "normal" output. In the fat periods, 40 gm. of the fat tested were included daily.

---

* From the Laboratory of Physiological Chemistry, University of Iowa.

[1] The chief one of these oils sold under trade names, in the Middle West, is Mazola.

The feces were marked off by lampblack, dried after addition of alcohol-acid, and extracted with dry ether in the usual manner.

Dog 1 was very vigorous and healthy. The weight before the tests was 6.1 kg., and after the tests, 6.8 kg.

TABLE 1.—TESTS WITH DOG 1

Fat Used	Length of Period, Days	Total Fat Excreted per Day, "Normal" Fat, Gm.	Excreted Fat, Less "Normal" Fat, Gm.	Percentage Total Fat		Percentage Total Fat Less "Normal" Fat	
				In Feces	Absorbed	In Feces	Absorbed
None	5	.282					
Cottonseed oil	3	.936	.654	2.3	97.7	1.6	98.4
Corn oil	3	1.108	.826	2.8	98.2	2.0	98.0
Lard	3	1.828	1.546	4.6	95.4	3.9	96.1
Corn oil	3	.877	.595	2.2	97.8	1.5	98.5

Dog 2 was in very poor physical condition, lean and mangy, becoming worse toward the end of the experiment. The weight before the tests was 5 kg., and after the tests, 4.75 kg.

TABLE 2.—TESTS WITH DOG 2

Fat Used	Length of Period, Days	Total Fat Excreted per Day, "Normal" Fat, Gm.	Excreted Fat, Less "Normal" Fat, Gm.	Percentage Total Fat		Percentage Total Fat Less "Normal" Fat	
				In Feces	Absorbed	In Feces	Absorbed
None	3	.632					
Cottonseed oil	3	1.101	.468	2.8	97.2	1.2	98.8
Corn oil	3	.937	.305	2.3	97.7	0.8	99.2
Lard	4	1.168	.536	2.9	97.1	1.3	98.7

Dog 3 was healthy, but very fat, slow and sluggish. The weight before the tests was 6.15 kg., and after the tests, 5.9 kg.

TABLE 3.—TESTS WITH DOG 3

Fat Used	Length of Period, Days	Total Fat Excreted per Day, "Normal" Fat, Gm.	Excreted Fat, Less "Normal" Fat, Gm.	Percentage Total Fat		Percentage Total Fat Less "Normal" Fat	
				In Feces	Absorbed	In Feces	Absorbed
None	3	.951					
Cottonseed oil	3	1.310	.359	3.4	96.6	0.9	99.1
Corn oil	3	1.029	.068	2.6	97.4	0.2	99.8
Lard	3	1.502	.551	3.8	96.2	1.4	98.6

If we take as a measure of nonmetabolized fat the amount that is excreted in the feces minus the amount that the dogs eliminated when they were on practically a fat-free diet, we find the percentage of fats metabolized, as given in Table 4.

TABLE 4.—PERCENTAGES OF FATS METABOLIZED

	Corn Oil	Cottonseed Oil	Lard
Dog 1	98.0 98.5	98.4	96.1
Dog 2	99.2	98.8	98.6
Dog 3	99.8	99.1	98.6
Mean	98.9	98.8	97.8

If we take the total amount of fat fed as the basis, neglecting that of the feces on the basic ration, the digestibility will appear somewhat less, but the relative digestibility will be the same. The difference in melting points may be the important factor in affecting this.

Other experiments, which need not be detailed here, show that corn oil can be well substituted for other animal and vegetable oils in salads and for "shortening" in cooking wheat foods.

Clinical Notes, Suggestions, and New Instruments

UNUSUAL CASE OF UMBILICAL HERNIA: RUPTURE OF SKIN

W. J. McGrath, M.D., Elkader, Iowa

Mrs. M., aged 78, whose family history was negative, had always been fairly well except for an umbilical hernia, beginning about forty years before, which had become quite large recently. The patient strained while at stool, causing a complete tear of the hernial coverings, including the skin, permitting 15 feet of the intestine and a large part of the omentum to escape from the abdomen.

The patient was seen shortly after the accident by Drs. Kriebs and Thine. No attempt was made at this time to replace the herniated intestine and omentum, but the patient was given morphin hypodermically, and the mass was wrapped in gauze wet with physiologic sodium chlorid solution.

About four hours elapsed between the time of the accident and the time I saw the patient. She was immediately placed on a kitchen table, and under light ether anesthesia the abdominal tear and the hernial ring were enlarged, the extruded intestine was replaced in the abdomen, and after the loosening of extensive adhesions and the removal of large shreds of torn omentum, the wound was closed. The patient was given 3 pints of physiologic sodium chlorid solution by hypodermoclysis before leaving the table. Recovery has been gradual but uneventful.

BACTERIAL TOXIN AS A CAUSE OF RETINAL HEMORRHAGE

Arthur S. Tenner, M.D., New York

In a recent article,[1] Dr. Lewis of Buffalo called attention to the obscure etiology of retinal hemorrhage and set forth a new conception, namely, that there occurs in these cases absorption into the blood of a soluble protein poison, usually given off from a focal infection, which has a solvent effect on the intercellular cement substance of the cell wall, and that the hemorrhage is not due to alteration of the blood pressure but to local lysis in the wall itself.

Even if no confirmatory pathologic evidence is presented, this theory is worthy of consideration. The ophthalmologist is often at a loss to assign any cause to his case of retinal hemorrhage.[2] When high blood pressure, arterial sclerosis or constitutional disease coexist, he has been content to attribute the hemorrhage to one of these, without further inquiry as to their mode of action. I am convinced that retinal hemorrhage is not dependent on blood pressure. I am not ready, however, to designate, as Dr. Lewis does, diabetes, arteriosclerosis and nephritis merely as associated conditions. They may not always be the active factors, but it is premature to exclude them entirely from the etiologic list. In the subjoined case, all such conditions were carefully excluded and the only seemingly possible factor in producing the hemorrhage was a focal infection, yet the case differs decidedly from Lewis' cases in that the active organism was a nonhemolizing streptococcus, from which could not occur the solvent action and the local lysis in the cell wall of which he speaks.

REPORT OF CASE

J. J., man, aged 54, referred to me at the Mount Sinai Hospital Dispensary by Dr. Joseph Davidson, June 17, 1918, for headache and poor vision, while in apparently the best of health, had suddenly become blind in the right eye, one week before. He had immediately visited one of the largest eye clinics in this city, where he had been told that a hemorrhage had taken place in his eye and he should put himself in the hands of an internist. This advice was followed, but the internist failed to find any ailment. The urine and the Wassermann reaction were negative. The systolic blood pressure was 110, and the diastolic 65. When I examined him, the right eye showed a recent preretinal hemorrhage, about half as large as the disk, in the region of the macula. The retina was edematous. The vessels showed no arteriosclerosis. The patient was able to count fingers at 18 inches. The left eye was normal in every respect.

---

[2] Fuchs: Ophthalmology, Ed. 5, p. 573, Note by Duane.

A search was then made for an infective focus. The rhinologist pronounced the sinuses negative. The mouth contained numerous decayed teeth, and there was a well marked pyorrhea alveolaris. Five teeth were extracted. The services of Dr. Harry Goldberg, dentist of the hospital, were then enlisted, and he and Dr. Vorhaus, pathologist, were successful in obtaining from an alveolar pus pocket a pure culture of a nonhemolytic streptococcus. A vaccine was made and administered to the patient. Eight weeks after the onset, six inoculations having been given, the clot had been completely absorbed and the vision was 20/20.

COMMENT

The points of this case are the absence of constitutional disease, the low blood pressure, and the presence of a pus focus, with the *Streptococcus anhemolyticus (nonhemolyticus)* as the active organism.

Preretinal hemorrhages are usually absorbed without injuring the retina permanently, in which case, vision is restored. Therefore I do not wish to lay any stress on the curative effects of the autogenous vaccine; but the rapid clearing of the retina and absorption of the clot, immediately subsequent to the inoculations, was nevertheless rather striking.

120 West Eighty-Sixth Street.

LUDWIG'S ANGINA: REPORT OF A CASE

H. T. Miller, M.D., Springfield, Ohio

An examination of textbooks and a review of the recent literature on Ludwig's angina show that the disease is not a common one, and that it is still usually regarded as fatal.

While there may be nothing unusual about this case otherwise, it is of decided interest that early recognition of the disease promptly followed by operation brought it to a safe issue.

I should not have recognized the disease so quickly had I not had the privilege of seeing a case of Ludwig's angina while on duty at the base hospital at Camp Greene, N. C. In this particular case the disease had advanced to such a degree that death immediately followed the operation. A postmortem showed the tongue, pharynx, larynx and trachea edematous and greatly congested.

In the present case the patient was seen on the fourth day of the disease. The tongue was quite swollen and pressed the mouth widely open; the submaxillary regions were edematous and greatly infiltrated so that the outline of the lower jaw was obliterated; the cervical region down to the clavicle and sternum was edematous.

The patient was operated on the day following his entrance into the hospital. As he was unable to lie down he was placed on the operating table in a sitting posture. Under unsatisfactory local anesthesia the low operation for tracheotomy was done. It was found necessary to cut through about 2 inches of edematous tissue before the trachea was reached. This gave immediate relief to the distressingly difficult breathing. Incisions on both sides of the inframaxillary regions were made extending from the angle of the jaw down to the hyoid bone. This step was followed by blunt dissection to deeper structures under the tongue. From these incisions only serum and dark blood escaped. On the fourth day there was a free discharge of pus, relieving all the distressing symptoms of pressure. Thereupon recovery was rapid and uneventful.

I feel confident that the successful issue of the case was due to the early recognition of the disease promptly followed by operation.

METHOD FOR PREPARING THE EOSINATE OF METHYLENE BLUE AND METHOD FOR STAINING

Foster A. Beck, M.D. (Windgap, Pa.)
First Lieutenant, M. C., U. S. Army; Chief of Laboratory, Post Hospital, Aeronautical General Supply Depot and Concentration Camp
Garden City, L. I., N. Y.

The length of time and the complicated technic, as formerly required for preparation of the eosinate of methylene blue, led me to devise a method by which this stain may be prepared ready for use in less than an hour.

The stain depends on the formation of methylene azure and methylene violet in the alkaline methylic alcohol eosin methylene blue solution. The eosinates of methylene azure, methylene violet and methylene blue are dissolved in the methylic alcohol, and the water-soluble products are precipitated and removed by filtration. The materials employed and the quantities are:

Reagent methylic alcohol (Merck)	95.000 c.c.
Tenth normal sodium hydroxid V. S.	5.000 c.c.
Eosin yellowish (water-soluble)	0.470 mg.
Methylene blue	0.400 mg.

The methylic alcohol is put into a 6-ounce bottle, the sodium hydroxid volumetric solution is added, and the two are mixed. To this solution the eosin is added and dissolved. As soon as the eosin is dissolved, the methylene blue is added, and the bottle shaken for thirty minutes. After filtration, the filtrate is put into a glass-stoppered bottle and is then ready for use. It is essential that the weights and measures be accurate. A buret should be used to measure the alcohol and sodium hydroxid volumetric solution.

METHOD OF STAINING BLOOD FILMS

1. The films should be made thin and even, and dried in the air. They should be protected from dust and dirt.
2. The dry film preparation is covered with the stain for one minute.
3. Tap water (distilled or rain water may be used) is added to the stain until the slide will hold no more without overflowing. The drops of water should be added rapidly.
4. At the end of two minutes from the beginning, the stain is flushed off with water, and the film is washed until it has a pinkish tint.
5. For making a differential leukocyte count after staining the specimen I shake off the excess of water, dry the undersurface of the slide with a towel, and make the count with the low or high power dry lens. The water on the stained surface makes an excellent refractive medium. The end of the lens should never be allowed to come in contact with the water.
6. For studying the minute structure of the erythrocytes, leukocytes and examining for malarial parasites, the specimen should be permitted to dry in the air or blotted dry with filter paper and examined with oil immersion.

Red cells are light rose, neutrophil granules a darker shade of rose, nuclei various shades of blue, eosinophil granules bright red, blood platelets blue, and lymphocytes blue. In malaria parasites the cytoplasm is blue, the granules dark blue, and the chromatin red.

For staining pus, spinal fluid for the meningococcus, throat smears, sputum, and smears made from cultures, one should proceed as described above.

In pus and epithelial cells the protoplasm stains a light shade of rose, and the nucleus blue. The gonococcus or other organisms within the pus cell stain dark blue, and the extracellular organisms various shades of blue. A distinct contrast is noticed between the organism and the cell.

ADVANTAGES

1. The method for preparing the eosinate of methylene blue as described saves time, requires less technic, and can be prepared by any laboratory technician.
2. Less time is required to stain the specimen, the old method requiring from three to ten minutes.
3. Tap water may be used instead of distilled or rain water.
4. For bacteriologic examinations this stain may be used instead of alkaline methylene blue.
5. For bacteriologic work heat is not necessary to fix the specimen.

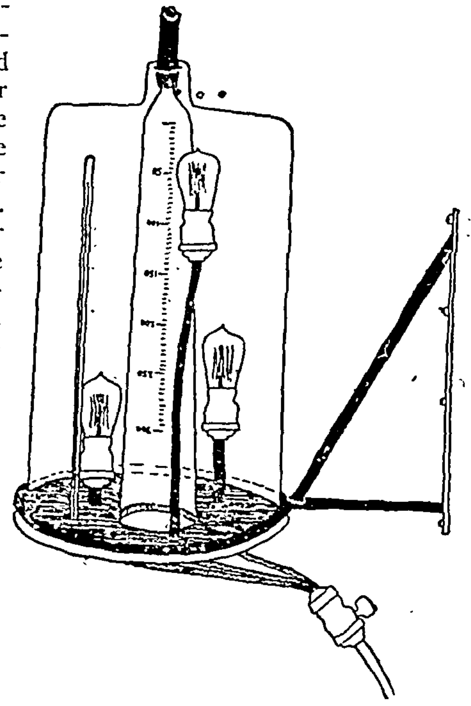
APPARATUS FOR ADMINISTERING ARSPHENAMIN AT TEMPERATURE OF BLOOD *

S. R. Thompson, M.D., Charlotte, N. C.

This apparatus was suggested on account of severe reaction and sometimes death after the administration of arsphenamin intravenously. Physicians are realizing more and more the necessity of introducing solutions that will be free from all possible sources of irritation. The reaction called "chills and fever" following intravenous injections of arsphenamin is due, we believe, to injecting arsphenamin intravenously below the normal temperature of the blood.

In giving ten or more doses of arsphenamin within from one to four hours we discovered that the patients receiving treatment when the solution was hot, or at the temperature of the blood, had no reaction or chill. Those receiving the last doses of the solution, which had cooled below the normal temperature of the blood, nearly always had more or less reaction. We have given more than a thousand doses by this method in dosages of from 0.3 to 0.6 gm. Solutions of from 30 to 150 c.c. have been given with chills or severe reaction in less than 5 per cent. of the cases.

The apparatus consists of a glass container practically closed with a wooden cover to prevent the entrance of cold air. In the center is a regular arsphenamin graduate. In the air chamber around this there are three 10 watt incandescent lights and a thermometer, registering in Centigrade and Fahrenheit. The lights may be attached or on separate switches. The rubber tubing, mixing jar, needles, etc., may be of any type desired. These are not included in the illustration. Before the injection is begun the solution in the rubber tube can be brought to the proper temperature by being allowed to run back into the graduate. Solution left in the apparatus will remain at the desired temperature, depending on the number of lights used.



Apparatus for administering arsphenamin at the temperature of the blood.

The simplicity, practicability and economy of this apparatus have commended it to us, and it has become indispensable in our clinic.

---

* Presented before the Mecklenburg County Medical Society, May 5, 1918.

* From the Crowell Urological Clinic and United States Public Health Clinic.

Venereal Diseases in Army and Civil Life.—In these five camps (Dix, Lee, Upton, Meade and Pike) there were about nineteen times as many cases contracted before enlistment as afterward. *It is, therefore, the disease contracted by civilians before enlistment, under civil conditions, which is responsible for the disability due to venereal disease in the Army.* To reduce the small amount of venereal disease contracted after enlistment is the problem of the Army. To cut down the vast amount brought in from civilian life is the problem before the state and local health officers throughout the United States. There is no greater or more urgent health problem before them today. To solve the whole problem, the Army and the health officers will need to exercise the closest cooperation.—Major W. A. Sawyer, M. C., U. S. Army, *Am. Jour. Pub. Health*, September, 1918.

Military Medicine and Surgery

THE EPIDEMIC OF INFLUENZA AT CAMP SHERMAN, OHIO

ALFRED FRIEDLANDER, M.D. (Cincinnati)
Major, M. C., U. S. Army; Chief of Medical Service
CAREY P. McCORD, M.D. (Detroit)
Major, M. C., U. S. Army; Chief of Laboratory Service
FRANK J. SLADEN, M.D. (Detroit)
Captain, M. C., U. S. Army; Assistant Chief of Medical Service
AND
GEORGE W. WHEELER, M.D. (New York)
Lieutenant, M. C., U. S. Army; Bacteriologist, Laboratory Service
CAMP SHERMAN, CHILLICOTHE, OHIO

At the time the prevailing epidemic of influenza was at its height in New England, numerous cases of coryza and bronchitis appeared at Camp Sherman. The picture was not characteristic of influenza, but the condition was so frequently noticed among the patients of the base hospital that isolation was instituted and special wards set aside for this purpose. The absence of the usual features of influenza led to considerable comment as to the justification of such a *diagnosis.* This uncertainty was abruptly and definitely terminated by the sudden appearance of large numbers of patients exhibiting characteristics of clinical influenza. Unlike the simple syndrome of the earlier cases, the new group was featured by sharper onset, prostration, aches and pains, and high temperature. By September 24 the transition had occurred, and this date marks the beginning of a definite epidemic of clinical influenza.

TABLE 1.—PNEUMONIA AT CAMP SHERMAN *

Date	Admissions	Pneumonia	Deaths
Sept. 24	80	0	0
Sept. 25	102	0	0
Sept. 26	216	8	1
Sept. 27	321	10	1
Sept. 28	314	9	3
Sept. 29	303	27	2
Sept. 30	732	97	7
Oct. 1	1,157	26*	15
Oct. 2	644	278	22
Oct. 3	633	55*	45
Oct. 4	957	461	52
Oct. 5	711	214	104
Oct. 6	449	152	119
Oct. 7	444	160	110
Oct. 8	169	73*	125
Oct. 9	81	220	97
Oct. 10	227	160	86
Oct. 11	78	51	53
Total	7,618	2,001	842

* Marked irregularity exists in these figures, but the variations in the daily occurrence of pneumonia are apparent and not real, being due to the system of reporting diagnoses.

At this time the population of the camp was 33,044. Of this number, 24,513 were white, and 8,531 were colored. The larger numbers of these men were inducted into military service from Ohio, but smaller groups from Pennsylvania, West Virginia, Alabama, Tennessee and Louisiana. Of the total population, 15,493, or 46.8 per cent., had been in service one month or less. From the nature of the examinations and procedures incidental to induction into service, it followed that these men were more closely and frequently grouped than the other men of the command. An analysis of the first 4,269 cases of influenza reveals that 2,944, or 69 per cent., occurred in men who had been in service one month or less. In other words, two thirds of these cases occurred in a group of 15,493 recent arrivals, comprising less than one half of the camp's population. This analysis also shows that the incidence of the disease decreased with length of residence in camp.

Table 1 shows, day by day, the admissions, the incidence of pneumonia, and subsequent deaths. In this table under "pneumonia" are included, without differentiation, the cases of acute inflammatory pulmonary edema described in the section on "Clinical Manifestations."

In addition to those cases admitted to the base hospital, other cases of influenza to the extent of 3,361 have been reported from the various camp organizations. The addition of this number to those admitted to the base hospital affords a total of 10,979 as the number of individuals affected in this epidemic.

Certain accrued statistics are of significance in relation to the extent of the epidemic (Table 2).

TABLE 2.—EXTENT OF INFLUENZA EPIDEMIC

	Per Cent.
Percentage of camp's population (33,044) affected in epidemic..	33.22
Percentage of camp's population admitted to base hospital (7,618)	23.05
Percentage of total affected developing either pulmonary edema or pneumonia (2,001)	18.22
Percentage of admissions to base hospital presenting or developing either pulmonary edema or pneumonia	27.57
Mortality in total number affected	7.66
Mortality among patients developing either pulmonary edema or pneumonia	42.07
Mortality in camp's population for period of epidemic.........	2.55

BACTERIOLOGY

During all stages of the epidemic, examinations have been made to establish the identity of the responsible organism. This organism has been sought in materials obtained from:

1. Smears and cultures from sputum of influenza patients.
2. Cultures from swabbings of throat and nasopharynx of influenza patients and immediate contacts.
3. Cultures from sputum of patients after development of pneumonia.
4. Blood cultures from patients after development of pneumonia.
5. Postmortem cultures from heart's blood, lung exudate, pleural fluid, pericardial fluid, spleen and kidneys.

1. Smears and cultures of sputum of influenza patients have uniformly exhibited the pneumococcus as the predominating organism. On typing, these pneumococci conformed to the following groups: Type IV, 80 per cent.; Type III, 18 per cent; Type II A, 2 per cent. One culture containing the pneumococcus as the predominating organism presented two colonies of Pfeiffer's organism. Certain immediate contacts with influenza patients were examined bacteriologically at a time when free from any manifestations of disease. Seventy-six per cent. exhibited pneumococci. Such of these as were typed were uniformly Type IV.

2. Cultures from swabbings of the throat and nasopharynx of influenza patients exhibited pneumococci in 54 per cent. and hemolytic streptococci in 4 per cent. of all examined. In none of these cases were influenza bacilli demonstrated.

3. On the detection of a complicating pneumonia, cultures were again made of the sputum. Regularly the pneumococcus was demonstrated with 80 per cent. characteristic of Type IV. Cultural conditions were suitable for the propagation of *Bacillus influenzae*, but in no instance was it detected.

4. Blood cultures were obtained from 100 patients after the recognition of a complicating pneumonia. In 6 per cent. of these cultures, growths were obtained. All were identified as pneumococcus Type IV. No other organisms have been detected in blood cultures, the remaining 94 per cent. being sterile.

5. Cultures obtained at necropsy from various thoracic and abdominal tissues and fluids indicated the presence of the pneumococcus as the dominating organism in 53.3 per cent of the bodies examined postmortem, while in 46.7 per cent. *Streptococcus hemolyticus* was the outstanding organism. The pneumococcus on being typed was classified as 75 per cent. Group IV and 25 per cent. Group III. In only one instance were both pneumococci and hemolytic streptococci encountered in large numbers in the same case. In this instance Group IV pneumococci and hemolytic streptococci were demonstrated in all cultures taken, heart's blood, lung exudate, pleural fluid, pericardial fluid, spleen and kidney. In conjunction with the Group IV pneumococcus isolated from the lung exudate of one body, numerous colonies of the *Bacillus influenzae* (Pfeiffer) were detected.

The persistent absence of influenza bacilli in the diverse materials examined militates against attributing this epidemic to the Pfeiffer organism. Cultural conditions favorable to the growth of influenza bacilli have been maintained. However, within the period covered by this report, this organism was exhibited in only two individuals. More consistently have the cultures yielded growths of the pneumococcus, to the end that significance is to be attached to the pneumococcus-streptococcus group of organisms as a dynamic factor in this epidemic. It may not be maintained at the present time that the pneumococcus has been the specific agent causing the epidemic, as prior to the epidemic a high percentage of this camp's population harbored Group IV pneumococci. The nature of the clinical manifestations and the processes evidenced at necropsy strongly bear out the contention that some member of the pneumococcus group has rapidly been distributed among the individuals of the camp, with activities of a character and severity not heretofore observed in this camp.

CLINICAL MANIFESTATIONS

The clinical manifestations observed necessitate a grouping into two form types. As already intimated, this epidemic was introduced by an atypical clinical picture characterized by mildness (Type I). The rapid spread gave a serious aspect to this simple catarrhal infection of the respiratory tract. The clinical features were fever, coryza, conjunctivitis, dry hacking cough, little or no leukocytosis and no noteworthy chest findings.

This type of infection was first noted among patients already in the hospital. It probably occurred also in the camp, as within a few days increasing numbers of such admissions required special provisions for their separate care.

The absence of prostration and aches and pains led some to regard the diagnosis of influenza as unwarranted. Gradually, however, the type changed, and within five days there was a full realization that an epidemic of influenza was in force. The transition seemed rapid, once it started, and the momentum the epidemic acquired was appalling. This second type (Type II), recognized as true influenza, was characterized by sharper onset, chills, quicker and higher rise of temperature, frequent epistaxis, distressing aches and pains, increasing prostration, red, glazed pharynx without tonsillitis, and an increase in the subjective manifestations of bronchitis, but still without noteworthy physical findings in the chest. Some cases of gastro-enteritis and a few of the so-called nervous form of influenza were observed.

At once two types of more seriously ill patients demanded attention. In the one (Type III), respiratory distress was marked, with meager signs in the lungs. At the most, suppressed breath sounds with fine râles in the lower axillary spaces were found. There was no local change in expansion, vocal fremitus, percussion, or transmission of whispered or spoken voice sounds. Such signs did not necessarily progress to pneumonic consolidation. The other severely ill type, at this stage (Type IV), was the outstanding clinical feature of the epidemic. This formed a distinct clinical picture not emphasized in any published reports. During the height of the epidemic, many patients exhibited on admission a strikingly intense cyanosis, especially noticeable in the lips. This was not the dusky pallid blueness to which one is accustomed in a failing pneumonia, but rather the deep blueness characteristic of methemoglobinemia. These patients had high fever, intense air hunger, complete exhaustion and prostration. They were semicomatose or in a low, muttering delirium. The lungs contained diffuse bubbling râles, increasing rapidly in number and extent, in addition to subcrepitant râles. The course was rapid to death in twenty-four or forty-eight hours. The patient was practically a drowning man. The picture resembled an acutely progressive pulmonary edema. With the increasing moisture in the lungs, however, there was no sign of myocardial insufficiency or dilatation. The pulse was fair in volume and tension. Cardiac outlines were unchanged. There were neither enlargement of the liver, nor serous effusions or edema in other portions of the body.

These clinical observations were supported by the necropsy findings in these cases.

At necropsy, those dead of the condition designated clinically as an acute inflammatory pulmonary edema presented lungs having one or more lobes dark red or bluish gray, firm and rounded, with no tendency to collapse. The pleural surface was smooth and glistening, not thickened, without exudate. The lung tissue pitted deeply on pressure. The process was essentially massive and confluent. There was no evidence of a lobular distribution. Section through an involved lobe revealed an extreme grade of congestion and edema. Immediately on section there was a free outflow of thin, dark red fluid from the cut surface. From 150 to 200 c.c. of this fluid were measured from a single section across the lung in the different cases. The cut surface was somewhat rough but not granular; there was no evidence of fibrinous exudation. Stained films of this thin fluid showed large numbers of red cells, very few leukocytes and epithelial cells, and many gram-positive cocci in pairs and short chains. The appearance of the bronchi was the same as that described in the general section on pathology below. The pericardium was normal throughout. The pericardial cavity contained from 25 to 30 c.c. of clear, straw colored fluid. No portion of the heart evidenced any enlargement. The myocardium presented normal color and consistency.

These cases occurred frequently during the first three days and persisted to a less degree throughout. They diminished as bronchopneumonia increased.

The condition was suggestive of that occurring after exposure to chlorin gas. In many, the serous fluid almost poured from mouth and nostrils on change of position, or bubbled out in the distressing efforts to breathe. The man struggled against asphyxia with all the accessory muscles of respiration. Some of the patients retained consciousness for a remarkable period, suffering intensely. In a word, it was as if the severity of the irritation in the respiratory tract was so caustic as to produce an immediate reaction, serous in character. It was essentially an acute inflammatory pulmonary edema.

COMPLICATIONS

The complication naturally to be anticipated in an epidemic of the respiratory type of influenza was pneumonia. By October 2, the pneumonias were so numerous as to occupy the entire bed capacity of the base hospital. Arrangements were then in force to admit influenza patients to an improvised annex and only pneumonia patients to the hospital. Shortly thereafter the available hospital beds were filled, and it was necessary to place 383 pneumonia patients in a special section of the annex. Secondarily the epidemic resolved itself into a pneumonia rather than an influenza problem.

A careful estimation of the circumstances would lead one to expect a secondary bronchopneumonia of virulent character, in an already acutely prostrated individual. This was the picture: The early cases in particular showed low leukocyte counts, low fever, and rapid pulse and respirations. The asthenia incident to influenza was so profound as to greatly diminish the resistance to the pneumonia.

A striking feature at this stage was the absence of physical signs to localize the particular area of involvement. A peculiar tympany with crepitant râles and distant bronchovesicular breath sounds was frequently all that was found. This was explained at necropsy by finding the pneumonic exudate in lobular distribution mainly about the hilum of the lung and progressively diminishing toward apex and base.

In the cases enduring longer than the average, as well as later in the epidemic, impairment of percussion was more frequently found, in varying superficial areas. With this were bronchial breathing and the other signs indicative of outspoken superficial consolidation. In many of these cases the consolidation was lobar in distribution, often distinguishable with difficulty from acute lobar pneumonia. In some a clearing by crisis occurred. However, as noted below, the pathology of the fatal cases of this type was distinctly different from that of acute lobar pneumonia.

Many of these patients lay in muttering delirium which persisted after the temperature was normal. This could be explained by the asthenia, although there were several instances of serous meningitis. Only once did secondary pneumococcal meningitis complicate the picture. Acute hemorrhagic nephritis was a frequent clinical observation.

Five cases developed subcutaneous emphysema without demonstrable pneumothorax. This was distributed over chest wall, neck and face, although in one case it involved the abdominal wall, scrotum and lower extremities.

Acute fibrinous pleurisy, even pleural pain, was not observed, except in a few instances in the latter days of the epidemic. At the date of writing, one case of empyema had appeared.

The more hopeful cases were frequently characterized by small patches of consolidation which completely cleared often in from ten to twelve hours. This was one of the striking features of the epidemic.

Other than pneumonia, complications to influenza were slight. Profuse epistaxis without nasal ulceration was very frequent at onset, and later acute catarrhal otitis media was common, but fortunately always cleared without perforation of the drum. Hemorrhages into the middle ear and a few instances of acute sinusitis occurred.

PATHOLOGY

The lesions of the lungs associated with the clinical picture of the acute inflammatory pulmonary edema are so pertinent in their relation to that condition that their description has been included in the foregoing description of the clinical manifestations.

In the necropsies of those patients that died of pneumonia the lesions noted in the lungs were those of a confluent bronchopneumonia involving one or more lobes. In the average case more than 50 per cent. of the lung tissue was involved and frequently as much as 90 per cent. The order of frequency of lobe involvement in this confluent pneumonia was right lower, left lower, right upper, left upper, right middle. In addition to this massive confluent process, there were patches affecting only a few lobules scattered throughout the remainder of the lungs, which resembled the ordinary type of bronchopneumonia.

The lobe affected with the confluent pneumonia was rounded, tense and firm, with no tendency to collapse; it pitted on pressure and did not crepitate. The affected lobe, when placed in water, invariably sank. The pleura was smooth and glistening; a few presented a beginning fibrinous exudate. The color of the involved lung in some was a deep red, in others a deep bluish gray, giving the lung a cyanotic appearance. Lobular outlines were indistinct or wholly obliterated. At rare intervals in a confluent involvement, isolated lobules would be unaffected.

On sectioning the lung there occurred an immediate exudation of dark bloody fluid. In those patients characterized clinically as having pulmonary edema, this exudation was profuse to the extent of the spontaneous outflow of from 150 to 200 c.c. of this thin, dark red fluid. The consistency of the lung tissue was that of soft muscle and not friable. On scraping the surface with a knife only a thin bloody exudate was expressed; no air bubbles nor fibrinous plugs. The scraped surface was dull and somewhat rough, but not granular. The color was a deep red, showing in places small areas from 4 to 5 mm. in diameter which were firm in consistency, almost black, and slightly raised above the surrounding tissue. These were noted more frequently adjacent to the smaller bronchi. The blood vessels of the affected lobe were dilated and contained dark fluid blood.

In the discrete lobular type of involvement, the affected lobules were distinctly raised above the surrounding lung tissue and were rather firm and resistant to the touch. The color, consistency and appearance on cut section were similar to those of the confluent lesion described above, excepting that the amount of fluid exudate was much less. These discrete areas were more numerous near the hilum of the lung and diminished in number and size toward the apex and base.

The portions of the lungs not affected by the pneumonic process showed varying degrees of congestion and edema. At times the amount of congestion was surprisingly small, even in those portions of the lung that were contiguous to the involved areas.

The bronchi contained thin, frothy, blood-tinged fluid, no mucus, no purulent material. The mucous membrane of the trachea and larger bronchi was swollen, causing distinct narrowing of the lumen. The color was pink, deep red or purplish, the small blood vessels showing intense injection. The smaller bronchi were dilated, the walls thin, and the swelling and injection of vessels not so prominent as in the larger tubes.

Most cases showed a complete absence of pleural involvement, and no excess of fluid, nor adhesions. In one case the right pleural cavity was filled with thin pus from which a pure culture of pneumococcus was obtained.

The pericardium presented no indication of involvement. The pericardial cavity contained from 15 to 60 c.c. of clear straw-colored fluid at times slightly greenish. The heart usually presented trivial enlargement on the right side; the right auricle was distended with blood; the right ventricle presented moderate dilatation; the myocardium was red or brownish red, bled easily and was usually of firm consistency. On occasion the right ventricular wall was moderately thin and flabby. The valves and cavities of the heart presented no characteristic findings.

The liver and spleen presented varying degrees of congestion, but were without other significant findings. The kidneys in a number of necropsies exhibited a beginning acute hemorrhagic nephritis.

Other accrued data from these necropsies of a general nature have been omitted as not pertinent to this report. This report is based on the first twenty necropsies of this epidemic. The early ones of the series were uniformly on deaths from pulmonary edema, while the latter half of the series predominately conformed to the confluent bronchopneumonia type.

THERAPY

1. *Influenza.*—Great care was taken to avoid undue exposure in these cases. Rest in bed, indoors, free purgation, gargles, acetylsalicylic acid and Dover's powders (pulvis ipecacuanhae et opii, U. S. P.) constituted the general plan of treatment. It is important to emphasize the fact that many of these patients, after two or three days of normal temperature, and during apparent convalescence, developed bronchopneumonia. This led us to take great care, retaining the patients in the hospital for seven days after defervescence, with frequent periodic chest examinations.

2. *Acute Inflammatory Pulmonary Edema.*—This presented a new problem in therapy. The principles of treatment employed in pulmonary edema incident to dilatation of the heart, though seemingly not indicated by the condition in question, were employed. Digitalis, a soluble caffein salt, morphin and venesection were without significant value. This was equally true of large doses of atropin. Oxygen was of temporary value. Posture accomplished drainage but did not influence the end-result. Pituitary solution, hypodermically, was suggested by the similarity of this condi-

tion to the results of gassing. No benefits were gained by its use. This general lack of response to treatment was to be expected, however, when one realizes that the patient in acute inflammatory pulmonary edema is constantly exposed to the respiratory irritant. The mechanical emptying of the bronchi by vomiting induced by ipecac was regarded as contraindicated on account of its heroic character. This condition must be regarded as the most fulminant type of respiratory influenza, against which no especial measure was of avail.

3. *Secondary Acute Bronchopneumonia.*—The usual recommendation as to diet, fresh air, rest, mild purgation and elimination were issued to all ward surgeons. All cases were digitalized, and reliance placed on soluble caffein salt for quick stimulation. Strychnin in large doses hypodermically had a distinct value in the existing asthenia.

GENERAL MEASURES

When it became evident that the epidemic would be apt to assume large proportions, the camp commander appointed a board (of which two of us were members) to formulate provisions for emergency camp sanitation and provide adequate facilities for handling large numbers of patients. This board had plenary powers. Its recommendations were at once put into effect by a series of orders issued by the camp commander.

The more important recommendations of the board may be thus summarized:

The camp was quarantined. Soldiers were not permitted to leave camp, and only relatives of very ill patients were allowed to enter.

Theaters, post exchanges, Y. M. C. A. buildings, etc., were closed, and congregating of soldiers within doors was forbidden.

All barracks were thoroughly cleaned and all overcrowding of well soldiers eliminated. A considerable number of the command was put under canvas.

Continuous ventilation of barracks was insisted on, responsibility for proper execution of orders being placed on organization commanders.

All tents were ordered furled during the day.

All bedding and clothing was given a daily sunning and airing, weather permitting.

All members of the command were required to gargle twice daily with a 1 : 10,000 quinin gargle. This was done because routine throat cultures early in the epidemic had shown that the pneumococcus was consistently present in large numbers in most of the throats examined. The pneumococcidal value of quinin in weak solution is thoroughly established.

Dry sweeping of barracks was forbidden, damp mops being used.

All roads in and around the camp were sprinkled twice daily to keep down dust.

An entire section of camp was at once emptied of troops, and the barracks thus obtained were fitted up as hospital wards. In all, 5,200 beds were thus provided. This annex to the base hospital was put under immediate charge of the commanding officer of Evacuation Hospital No. 28, which was mobilizing at this camp. The personnel of this organization was augmented by sending medical officers from line organizations and the base hospital. The annex was under general control of the officials of the base hospital.

The base hospital itself was given over almost entirely to the care of pneumonia patients. All porches were filled with beds, without undue crowding, and the provisions of 1,000 cubic feet of air in wards rigidly adhered to.

The base hospital thus equipped had a capacity of 2,400 beds, of which 2,000 were available for pneumonia patients. Sheet cubicling of wards and porches was systematically carried out.

The general plan contemplated the using of the annex for the milder cases, transferring all pneumonia patients, known or suspect, back to the base hospital. At the height of the epidemic this was found to be impracticable, and three barracks (300 bed capacity) were set aside in the annex for the handling of pneumonia patients. To these barracks special medical officers and trained nurses were assigned.

In the base hospital proper, one ward surgeon was assigned to each pneumonia ward. The emergency necessitated the use of many medical officers in a field far removed from their usual spheres of activity. The system of ward supervisors, general and special consultants as devised, made it possible to secure for the patients the maximum amount of proper medical treatment.

SUMMARY

In this epidemic of clinical influenza occurring in an Army camp with a population of 33,044 soldiers, 10,979 men (33.22 per cent.) contracted the disease. Secondary to the influenza there occurred a high incidence of pneumonia, affecting 2,001 (18.22 per cent.).

The outstanding features of the epidemic were:

1. Of the camp's population (33,044), 15,493 (46.8 per cent.) were men who had been inducted into service within the previous month. This group of men contributed 2,944 (69 per cent.) of the first 4,269 cases occurring in the camp. That is, two thirds of this group of cases occurred from a group of men comprising less than half the camp's population. The incidence of the disease decreased with the length of residence in camp.

2. The severity of the infection occasioned a high mortality. During the epidemic, 842 deaths occurred, 7.66 per cent. of the total number affected in the epidemic and 2.55 per cent. of the camp's population. All deaths were attributable to acute inflammatory pulmonary edema or to pneumonia.

3. *Bacillus influenzae* (Pfeiffer) has not been demonstrated as the causative organism. The frequency of its detection has not exceeded the frequency of its existence under normal conditions.

4. Pneumococcus, chiefly Type IV, has been the predominating organism. From the sputum the pneumococcus has been recovered uniformly. In necropsies the pneumococcus was detected in 53 per cent. of instances. The hemolytic streptococcus occurred in 47 per cent. of thoracic exudates.

5. The clinical manifestations necessitate a division into four types, which represent a progression in severity. Type I, characterized by coryza and bronchitis, was the forerunner of the true influenza (Type II). Type III comprised a group with subjective signs without demonstrable objective evidence of pneumonia. Type IV, acute inflammatory pulmonary edema, represented the most fulminant type of respiratory influenza.

6. The intense asthenia produced by the influenza influenced both the picture and the outcome of the secondary bronchopneumonia.

SCABIES IN MILITARY AND CIVIL LIFE

ITS DIFFERENTIATION, COMPLICATIONS AND TREATMENT

FRANK CROZER KNOWLES, M.D. (PHILADELPHIA)
Captain, M. R. C., U. S. Army; Dermatologist, U. S. Army Base Hospital No. 10
FRANCE

War is the great teacher of efficiency. The greater the man power that can be kept in the field and the fewer men that have to be sent to the rear for disability, the sooner will victory end this world war. There is probably no greater problem today in the fighting forces in Europe than the group of animal parasitic diseases. It has often been said that intense itching which keeps the patients awake night after night is harder to bear than pain. There seems to be a rather chaotic condition present as to the understanding of the clinical manifestations of scabies, its differentiation from the various forms of pediculosis, its complications and its treatment. The various animal parasitic conditions attacking the skin should be under the care of trained dermatologists rather than being distributed haphazard among all of the general hospitals. If the excellent suggestions typed by Major H. MacCormac, R. A. M. C., were followed minutely, the cure of scabies would be very much hastened.

During the last fifteen years I have personally treated in civil hospital practice, in my various hospital clinics and dermatologic wards of eighty beds, 8,000 cases of scabies. The incidence of this disease has been a little more than 5 per cent. of the total dermatologic cases observed during this time. During our twelve months tenure at this large British general hospital, there have been somewhat more than 2,000 cases treated in the skin department, and of this number over 500 have been scabies. If conditions secondary to scabies, such as furuncles, impetigo, folliculitis, septic sores and so-called inflammation connective tissue (I. C. T.) were included, almost 1,000 more of these cases would be classified under the former heading. In other words, 1,500 of the 2,000 dermatologic cases were either frankly scabies or secondary to scabies.

TABLE 1.—DIFFERENTIATION BETWEEN SCABIES AND PEDICULOSIS CORPORIS

Scabies	Pediculosis Corporis
General in distribution, exclusive of the face and scalp.	General in distribution, exclusive of the face, scalp, hands, feet and the lower arms and the lower legs
Predilection for the webs of fingers, flexure surface of the wrists, penis, flexure surface of extremities, and anterior surface of trunk	Predilection for extensor surface of the upper arms and upper legs, and posterior surface of the trunk, particularly across the shoulder and lower back
Diagnostic sign the "burrow," a minute zigzag line, consisting of alternating blackish and whitish dots, the width of a thin thread, and from the smallest fraction to ⅛ inch in length; itch mite too small to look for; pinpoint in size	Diagnostic sign the pediculus, small pinhead in size, found in the seams of the clothes more frequently than on the body
The eruption we speak of as multiform; papules, vesicles and pustules, boils and large crusts	The eruption consists chiefly of long, linear scratch marks, small punctate hemorrhages and excoriations; not infrequently crusts and boils
Itching severe, usually at night	Itching severe, usually at night

Table 1 will elucidate the differentiation clearly between pediculosis corporis and scabies.

Scabies in military and in civil practice differs considerably, as shown by Table 2

Scabies is readily differentiated from pediculosis, for, in the latter disease, the diagnosis is based on finding the small pinhead-sized ovum ("nit") attached to the hairs in the pubic or axillary regions; in hairy individuals, any hair on the entire surface of the body, exclusive of the scalp, may show this nit. In a recent series of 200 patients minutely examined, pediculosis pubis was present in 190 of the cases.

TABLE 2.—SCABIES IN CIVIL LIFE AND IN MILITARY LIFE

Scabies in Civil Life	Scabies in Military Life
Eruption usually on the lateral aspect and webs of fingers, consisting of pustules and burrows, excepting in those unusually cleanly, in washerwomen, and mechanics who work in oils, greases, graphite, etc.	Hands are involved in but few cases
Penis frequently shows only one or two pustules and burrows and occasionally none	Penis usually shows a marked involvement, numerous pustules and burrows
Complications are absent in most cases	Complications, such as an unusually large number of pustules, boils, impetigo, and the so-called I. C. T. (secondary pustular lesions) are frequently present

METHOD OF TREATING SCABIES

On the first day the patient is given a warm bath with plenty of soap. One rubbing is given with sulphur (precipitated sulphur, 1 dram to the ounce of petrolatum).

On each of the next three days a sulphur rubbing is given.

On the fifth day a warm bath with plenty of soap, and clean clothes, are given.

Thorough and minute examination of the entire body is made to insure that no active disease remains. If active lesions are still present, four more days of sulphur rubbings are given, followed by another warm bath, another careful examination of the skin surface, and clean clothes.

Method of Rubbing.—A noncommissioned officer, orderly or myself is always present as the patient rubs himself or is rubbed. A minimum of fifteen minutes is taken for the rubbing of each patient. The ointment is rubbed in thoroughly on every portion of the entire cutaneous surface, from the collar line downward; not even the smallest part is missed. The ointment is rubbed in with sufficient friction to open up and destroy all of the burrows. A thin coating of this ointment is purposely allowed to remain over the entire skin surface, excepting the face and scalp (areas that are never attacked excepting in breast-fed babies), after the rubbing is completed, so that if any of the acari have escaped they will be suffocated by the sulphur fumes. In addition, when there are a considerable number of pustules and boils present, the areas so involved are bandaged with sulphur ointment after the daily rubbing is completed.

The greatest care is exercised in treating scabies in a separate hut or tent, in the thorough disinfection of all articles of clothing, and in the use of separate baths.

Treatment of the Complications of Scabies.—There is no more efficient remedy for the treatment of all secondary pustular conditions following scabies than ammoniated mercury ointment, from 20 to 40 grains to the ounce of petrolatum. Boils in their incipience are best cured by rubbing in thoroughly each day for ten minutes a 25 per cent. ichthyol ointment; in a later stage they require opening. If boils continue to recur or a large number are present, autogenous vaccines are indicated. Septic ulcer and inflammation connective tissue not infrequently require rest in bed and the local application of ammoniated mercury, 20 grains to the ounce of zinc oxid ointment.

The efficacy of treating scabies, in the method outlined above, is proved not alone by the cure of 8,000 cases in civil practice but by the result obtained in the minute care of the last 150 cases treated in this hospital. Twenty-five per cent. of the latter patients were discharged cured in five days; 50 per cent. in nine days, and 15 per cent. in sixteen days. The remaining 10 per cent. required from three to six weeks. The length of time required in the latter cases was due to the large number and severity of the primary or secondary stayphylococcic lesions, such as boils, impetigo, septic ulcers, folliculitis and inflammation connective tissue.

SUMMARY

1. Scabies should be treated by the routine suggested by the leading dermatologists of Great Britain, France and the United States.
2. Scabies is a greater problem in military than in civil life because of its greater frequency and severity.
3. Scabies is rather atypical in military life because of the comparative freedom of the hands and more marked involvement of the penis.
4. Complications secondary to scabies are much more frequent and markedly more severe in military than in civil practice.
5. A rather prolonged convalescence is observed in approximately 10 per cent. of scabies in military practice.

NEW METHODS FOR BLOOD TRANSFUSION AND SERUM THERAPY

FRANK W. HARTMAN, M.D.
Lieutenant, M. C., U. S. Navy
WASHINGTON, D. C.

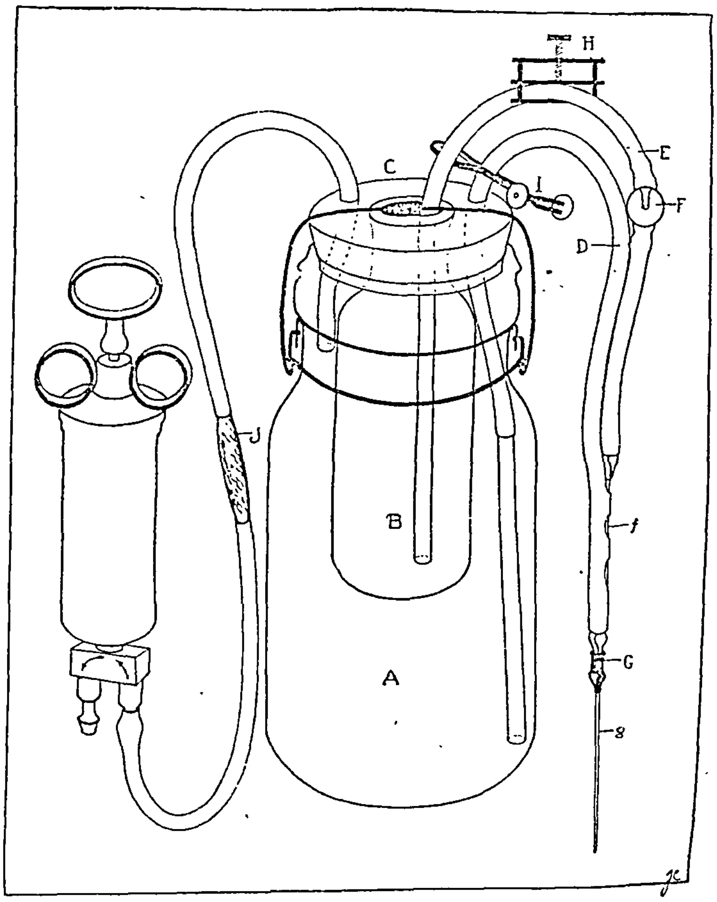
1. A ONE MAN CLOT PROOF TRANSFUSION APPARATUS

In working more or less constantly during the past year with blood transfusion by the citrate method, we have found numerous pitfalls and have tried to simplify the apparatus, eliminating chances of failure.

The principal difficulty has been to use a needle small enough so that one trial is enough to get well into the vein and still prevent clotting long enough to get the desired amount of blood. A 17-gage needle (*g*), preferably platinum, is large enough and causes the donor no marked discomfort. However, as the blood reaches the tube leading to the container there is a slowing of the stream because of the large bore of the tube compared with that of the needle. The walls of this tubing soon become coated with blood cells and a clot filling the lumen results, often before the desired amount of blood is drawn.

With these facts in mind, the apparatus shown in the illustration has been devised, which provides for citrating the blood to any degree, at the needle. Not only does this prevent clotting in the tubing but it also does away with the necessity of agitating the container while the blood is being drawn.

A one or two quart E. Z. seal fruit jar (*A*) is used as a container. A 12-gage rubber stopper (*C*) fits the neck of this jar perfectly. A large hole is bored in the center of the stopper and the neck of a round 4-ounce bottle (*B*) fitted into it. Two small holes are bored through the stopper, one for the pressure tube and a second for the blood-carrying tube. The tubes are passed directly through the stopper because we find sterilization only causes the rubber of the stopper and tube to fuse, whereas glass tubes passed through it sear the surrounding rubber on sterilization, and soon leakage occurs. The bleeding tube (*D*) may be continuous from the needle to the bottom of the container, or may have a glass tube attached inside as illustrated. It is found convenient to have a connection at the distal end of the bleeding tube so that needles may be exchanged at any time. A second needle (*f*) of any size may be used to lead the citrate into the bleeding tube. From this a rubber tube (*E*) passes to the bottom of the citrate bottle (*B*). This tube is broken by a small dropper (*F*), such as is used on the Dakin irrigating apparatus, so that as the flow of citrate is regulated by the stopcock (*H*), we may be certain that the citrate is never completely cut off.



Apparatus for blood transfusion and collection of plasma.

The pressure tube just pierces the stopper, and may be broken by an elongated glass bulb filled with cotton (*J*). With this precaution, suction and pressure may be made by mouth if pump or bulb is not available. An ordinary aspirating pump answers very well.

From 15 to 20 c.c. of 2.5 per cent. sodium citrate solution are placed in the jar (*A*), the citrate bottle (*B*) is filled with the same solution and the stopper loosely fitted to the mouth of the jar. The needle is protected with gauze or cotton and the whole wrapped and sterilized. When the actual operation is undertaken, the stopper is fitted more tightly and clamped down with the lid wire of the jar. The citrate in the jar is forced over to fill the tubes and needle and the tube clamped off at *I*. The apparatus is set on the operating table in the angle between the donor's arm and his body. A prominent vein is chosen and the surrounding skin cleansed with iodin and alcohol. The needle directed toward the body, is plunged into the vein, the clamp (*I*) released, and gentle negative pressure produced in the bottle. A generous flow of citrate is allowed through *F* until the blood is seen to be coming over properly; then the flow is regulated so as to obtain approximately 10 c.c. to each 90 c.c. of blood drawn, erring only in excess. The jar and citrate bottle are graduated with a file or diamond point.

The desired amount of blood being obtained, the pump is reversed, the citrate tube clamped off at *H*, the needle changed, and the blood tube and needle filled with the citrated blood and clamped at *I*. The patient's vein is needled, and after release of the clamp (*I*), the solution is forced from the bottle with low, even pressure. The use of the fruit jar furnishes a cheap and efficient container which is readily obtainable in large quantities. The lid clamp precludes any trouble with leakage about the stopper, regardless of the amount of negative or positive pressure exerted; and in case the blood is stored, the usual glass lid and rubber washer may be clamped on, sealing the jar quickly and securely.

2. COLLECTION OF HUMAN PLASMA FOR THERAPEUTIC USE

In the present influenza epidemic it occurred to us to try citrating the blood and sedimenting the cells in order to obtain plasma from convalescent pneumonia patients rather than obtain it by the usual clot and centrifuge method. The apparatus is especially adapted for the purpose, since jar after jar of blood may be obtained by merely shifting the stopper from one sterile jar to the next, drawing the blood and in turn sealing them with the glass top. It was soon found that dilution hastened by sedimentation, so that by using a 1 per cent. sodium citrate solution in physiologic sodium chlorid solution, 25 c.c. to 75 c.c. of blood, the cells settle to the lower half of the mixture in twelve hours' time when kept in the ice chest. For example, when 500 c.c. of blood are drawn, 125 c.c. of the citrate-sodium chlorid solution are used, and from the 625 c.c. mixture we obtain on an average 312.5 c.c. of serum and citrate-sodium chlorid solution mixture. This mixture is about one third citrate-salt mixture and two thirds plasma; hence from the 500 c.c. of blood drawn we obtain 200 c.c. of serum after twelve hours' sedimenting. The yield of serum obtained by the clot and centrifuge method as carried out in Boston recently has been about 300 c.c. per thousand c.c. of blood or 150 c.c. per 500 c.c. of blood. The supernatant fluid is decanted or drawn off with bulb pipets.

The advantages are the facility of obtaining the blood, the small amount of apparatus required (large centrifuges with suitable heads are only occasionally available), the small amount of handling necessary, and the large yield of plasma obtained.

Any number of jars are obtainable, and donors are bled in rapid succession with a single stopper by refilling the citrate bottle and occasional cleaning and boiling as a precaution against clotting and contamination. The plasma is used without regard to group or compatibility. Two cases, each complicated by empyema, among twenty-two treated with this plasma, were lost.

3. TEST PAPERS FOR THE RAPID SELECTION OF DONORS

It is always desirable to match blood directly if possible, and a modification of Lee's method is used, 2 drops of the patient's serum and 1 drop of the donor's red cell suspension (1 drop of blood to 1 c.c. of citrate-sodium chlorid solution) being placed at one end of a slide, and 2 drops of the donor's serum and 1 drop of the patient's red cell suspension at the other, and being incubated in a moist chamber at 37 C. for one hour.

For the grouping of donors and recipients a method has been devised which is workable and should prove practical, for men at the front particularly.

The blood is drawn and citrated as for transfusion, and then set in the ice chest for several days to allow as complete sedimentation as possible. The supernatant plasma and citrate are drawn off, placed in a large porcelain dish, and evaporated to dryness with the electric fan. To the residue is added the smallest amount of physiologic sodium chlorid solution that will dissolve the residue. Grinding in a mortar facilitates the solution. Squares of heavy filter paper are saturated from this after the method of preparing amboceptor paper for the Noguchi test. This is allowed to dry between layers of unbleached muslin. The dried paper may be kept sealed in oiled paper envelops or in any moisture-proof container.

For grouping, strong agglutinating papers of groups of two and three are needed. The test consists in cutting a strip of filter paper 2 mm. wide and 2 cm. long of two and three groups. These are folded into a V, placed on a polished background, preferably white enamel or porcelain, and a drop of water added to each. A drop of blood is drawn from the person to be grouped and a small portion of it put into each group. Sufficient salt and citrate will have gone into solution to prevent hemolysis and clotting. The concentration of the serum is such as to cause marked agglutination easily visible to the naked eye in from three to five minutes if it is to occur.

From experience with amboceptor paper and antibacterial serums thus preserved for use in the tropics, we may expect this serum to retain its agglutinins indefinitely. A small package would be enough for many tests and can readily be sent through the mails. No glassware or solutions are necessary for the test.

Rectal Injection of Arsphenamin.—A. Azemar publishes in the *Annales de dermatologie*, 1918, **7**, 14, a report on the rectal administration of the novarsenobenzol brand of neoarsphenamin in the treatment of syphilis. He reports the details of thirty-six cases and gives a summary of the literature on the subject. The drug was rapidly absorbed from the rectum, appearing in ponderable quantity in the urine in two hours, but there was none after the sixth day. The therapeutic effect is less rapid, less profound, less constant and less durable than when the drug is administered by the vein. The intrarectal technic might be utilized during periods of latency and as preventive treatment, but he does not advise it as a general method or with active manifestations. His dose was usually 0.9 gm. for otherwise healthy adults, repeated at six day intervals. In seven tenths of the cases, five injections completed the cure. With doses less than this the results were disappointing. For children and debilitated adults, the doses were 0.6 or 0.7 gm. He added ten or fifteen drops of tincture of opium to the fluid. There were never any indications of intolerance at the time or later. Mercurial treatment might be combined with this technic, but he did not attempt it.

ANOTHER WORD REGARDING CREATINURIA

In contrast with creatinin, creatin is not a normal constituent of the urine of healthy adult men, though it makes its appearance as the result of disturbance of metabolism. It may be found in the urine of women and is commonly excreted by children. These well substantiated facts offer a chemical and physiologic puzzle that has given rise to much speculation and considerable experimentation. The hypotheses advanced need not be detailed again here. They differ fundamentally in one respect, namely, as to whether the eliminated creatin is primarily of endogenous or exogenous origin. Rose has thus formulated the controversy: The acidosis theory of Underhill,[1] and the carbohydrate deficiency theory as developed by Mendel and Rose,[2] agree in attributing urinary creatin in individuals on a creatin-free diet to an entirely endogenous source, namely, the creatin of the tissues. The theory of McCollum and Steenbock[3] and of Denis[4] suggests an exogenous origin of urinary creatin in certain amino-acids of the diet. It is universally recognized that in ultimate analysis tissue creatin must be synthesized from amino-acid; but the question at issue is, Does creatin formation proceed only so far as this substance is needed by the cells, or may the reaction be induced indefinitely by the introduction of creatin precursors? In other words, Is creatin an anabolic product formed for a specific purpose or function, or is it a normal product of the catabolism of protein, whether this protein be of tissue origin (starvation) or of food origin (high protein diet)?

After Denis had reported that in adults with exophthalmic goiter and in normal children, the creatin output can be greatly augmented by increasing the protein of the diet, while it is promptly diminished in amount or made to disappear entirely by lowering the intake of protein, and that diets rich in protein lead to the excretion of creatin in normal women but not in normal men, contradictory evidence was soon produced. Rose, Dimmitt and Cheatham[5] showed that, contrary to the generally accepted idea, the feeding of much protein to fasting men can result in the entire disappearance of creatin from the urine. These investigations, undertaken at the University of Texas, have now extended[6] to demonstrate clearly that the ingestion of diets excessively high in protein fails to induce the excretion of creatin in normal women and men. Diets yielding from 3,400 to 3,900 calories a day, whether accompanied by a moderate (13 gm.) or a large (27 gm.) nitrogen intake, exerted no appreciable influence on creatin-creatinin metabolism.

The Texas biochemists adhere to the belief that no evidence has yet been adduced sufficient to justify the acceptance of a theory that postulates an exogenous origin of urinary creatin in the absence of creatin in the diet. This is quite different from the contrary hypothesis that "on the ingestion of protein some fraction of this is transformed into creatin, transported to the muscles, and there absorbed. If so much creatin is manufactured that the muscles become supersaturated, creatin is excreted by way of the kidney." The burden of proof for such a view still remains with its advocates. Meanwhile the secret of the genesis of creatinuria is still to be sought in the study of metabolism.

FOOD AND THE HUMAN MACHINE

"Food is the fuel of the human furnace, and must be furnished to that furnace in accordance with its needs." If this dictum of physiologic science is correct, we may properly inquire whether the needs of man are far smaller than students of nutrition have taught of late,[7] or whether the energy metabolism of the German subject has assumed a uniquely low level in consequence of the war. One hears of the pronounced reduction in food allowance among the civilian population of the late Central Powers, and the implication is that the rationing schemes are carried out without detriment to the inhabitants. We need to learn the lessons which their experience, whatever it may be, can teach; for America and her allies also have their food problems.

What are the accepted facts? The basal metabolism or heat production of an average man weighing 156 pounds (70 kg.) will be 70 calories an hour at rest and without food, or 1,680 calories in twenty-four hours. The maintenance requirement when food is ingested may be augmented by 10 per cent. The basal requirement of energy may be reduced by undernutrition, and this process may largely economize food. To accomplish a given amount of work, however, a fixed amount of food fuel is required, irrespective of the nutritive condition of the organism.

[7] A valuable summary illustrated with charts, of what is known regarding the food requirement of boys from birth to 16 years of age, soldiers at hard work, and men and women in industrial pursuits is given by Lusk, Graham: The Fundamental Requirements of Energy for Proper Nutrition, The Journal A. M. A., March 23, 1918, p. 821.

It is reported that the German army received extra heavy rations prior to the commencement of the great offensive for Amiens on March 21 of this year, and the general advice is that that army has always been well provided with food. With the civilian population, however, the situation has been reported to be serious, and accounts agree that the worst shortage of food occurred in the spring of 1917. According to the published statement of a Munich clinician,[8] in October, 1917, the civilian ration at Munich contained protein, 56.7 gm., fat, 30.5 gm., and carbohydrate, 308 gm. It was made up of bread, meat, milk, potatoes, sugar, cheese, egg, butter and grits, and had a value of 1,760 calories. In January, 1918, it remained substantially unaltered. These astounding figures are corroborated by Jansen,[9] according to whom the official ration of Munich in the spring of 1917 contained 1,600 calories and 9.7 gm. of nitrogen, which is equivalent to 60 gm. of protein.

It is one thing to furnish a ration and another to nourish a population adequately with it. Jansen has thrown an illuminating light on the situation. The ration cited was given to several men who were occupied as interns in the medical clinic of Friedrich von Müller, and nitrogen balance experiments were carried out on them for from six to thirty-one days, as in the experiments of Chittenden. Prior to the observations the men had been for some time on short rations, especially as regards the protein components. It is stated, however, that the average loss in weight since the war began was about 5 kg., which certainly does not indicate excessive emaciation. The average weight of the subjects was 62 kg. While partaking of the foregoing diet each man lost weight daily and also very nearly 2 gm. of nitrogen. This loss was attributed to the deficiency of calories in the dietary, for the addition of 500 calories in the form of sugar resulted in maintenance of the body weight as well as in nitrogen equilibrium.

But the laws of the metabolism of energy are immutable. Two of the men, when partaking of the official Munich ration, undertook muscular exercise in the form of walking. Such exercise under ordinary circumstances would have been accomplished without effort. After walking three and five hours, however, the subjects felt obliged to return to Munich by train. Before the walk the basal metabolism had been determined as 1,400 calories a day. On the return to the laboratory the subjects were too excitable and irritable to lie quietly in the respiration chamber, but a determination of the basal metabolism of one of them was made twelve hours after the completion of the walk and showed an increase of 50 per cent. above the normal level.

It appears from these experiments that what is publicly proclaimed as the official ration of a German city must be supplemented to a very considerable extent by the purchase of unrationed foodstuffs if the day's work is to be accomplished. It is furthermore interesting to note the statement that two women interns had both gained in weight during the war. Since a woman needs less food than a man, any attempted equality in the distribution of foods would ensue to her benefit.

THE PARATHYROIDS AND IDIOPATHIC TETANY

However expressive the word "idiopathic" may be as an indication of definite symptoms or as the designation of a recognized clinical entity, it almost invariably leaves a query in the mind of the critical student as to the underlying cause or significance of what is described thereby. This has long been true of idiopathic tetany or spasmophilia. This hyperexcitable state of the nervous system is manifested by a spastic condition of the muscles of the extremities, by laryngeal spasm, and by epileptiform convulsions in its active state. In the more recently described latent forms there is merely an increased response to mechanical or electrical stimulation of the peripheral nerves. In childhood, idiopathic tetany is usually associated with rickets; in adult life, its incidence goes with dilatation of the stomach, pregnancy, certain infections, and a few occupations. These facts have long been known.

Of the many causes that have been assigned to this spasmophilia—disease of the brain, "rheumatism," metabolic derangements, specific infection, and endocrine abnormalities, the last has offered the greatest possibility of opening the way to a better understanding of the etiology. Although the possible association of the parathyroids with tetany was suggested by clinical workers as early as 1902, it has been the experimental physiologists who have made the more convincing contributions to the subject. So long as the independence of the thyroids and parathyroids was not clearly recognized and demonstrated, there was bound to be confusion in the investigation of the physiology and pathology of these organs. Now that the demonstration of their individuality and embryologically separate origin is accepted, it is worth while to consider more seriously the claims as to the relation of the parathyroids to the clinically recognized forms of idiopathic tetany.

There is agreement today among experimentalists that the nervous symptoms described often in the past as occurring after thyroidectomy are due to removal of the parathyroids. Too little attention has been paid to the noteworthy series of contributions from the Department of Physiology at the University of Glasgow which won the 1916 Warren Triennial Prize of the Massachusetts General Hospital for D. Noël Paton and his co-workers. They agree that all the nervous symptoms are undoubtedly due to the condition of the central nervous system. Section of the nerves to any part of the body entirely and immediately abolishes all spasms, tremors and jerkings of the muscles supplied. Consequently the condition of the peripheral neuromuscular mechanism is not likely to be the occasion for the primary action in the production of the symptoms. The parts played by the spinal, cerebellar and cerebral arcs are by no means yet clear.

Paton, Findlay and Watson[1] agree that undoubtedly the most constant change after parathyroidectomy is the increase in the response to galvanic stimulation. This hyperexcitability has long been referred to as a valuable sign of the condition of tetania thyreopriva, especially when other symptoms are not conspicuous. The Glasgow investigators, in their extensive researches on this subject,[2] have established that the absence of a direct relationship between the severity of the nervous symptoms and the electrical excitability of the peripheral neuromuscular mechanism is a clear proof that this altered excitability is a phenomenon of secondary importance to the changes in the central nervous system, and that it cannot be taken as a measure of the severity of these disturbances.

In searching for a further index to the causes of the symptoms recorded, attention has been centered on metabolic phenomena. According to the observations of Paton and his collaborators, we are encouraged to believe that there is no evidence of a direct controlling influence of the parathyroids over the central nervous system. The symptoms of the tetany following parathyroidectomy are also not primarily due to the loss of calcium from the body, as was postulated at one time. Paton and Findlay have observed, however, that the phenomena of guanidin poisoning correspond very closely with those of tetania thyreopriva. Furthermore, they found a marked increase in guanidin and methyl guanidin in the blood and urine of animals after removal of the parathyroids and also in the urine of children suffering from idiopathic tetany. Hence the conclusion that the parathyroids control the metabolism of guanidin in the body by preventing its development in undue amounts. In this way, they probably exercise some regulative action on the tone of the skeletal muscles. Finally, the same investigators suggest that tetania thyreopriva and idiopathic tetany are identical as regards their characters and metabolism, and although the histologic evidence is not conclusive, in all probability the parathyroids are implicated in both conditions. The metabolic history of the guanidin manifestations remains undetermined. A relationship between it and creatin has often been postulated. Perhaps this will be a profitable direction for the prosecution of future studies in this field, particularly since the striking similarity between an experimentally obtainable condition and a recognized clinical entity has been pointed out.

VITAMINS AND METABOLISM

The enthusiasm and concern that are awakened just now by the subject of vitamins in the discussion of nutrition are perhaps unequaled by any similar interest with the possible exception of that commanded by the idea of the calory. In reviewing the momentary status of our knowledge, Professor Steenbock[1] of the University of Wisconsin has remarked, with intelligent appreciation of the situation, that "as experimentation revealed symptoms attributable to vitamin deficiency, the general public, ever easily impressed by matters unexpected, and matters so vital as to revolutionize the conception as to what constitutes an adequate diet, soon became alarmed. At present it is probably not overstating the situation when it is said that the previously considered all-important attributes of an adequate ration, such as sufficient protein, calories and salts, have probably been slighted by the sudden interest taken in vitamins."

In the immediate past the attention of scientific investigators has been directed in greatest measure to the discovery of the occurrence and distribution of those properties of foods to which the name vitamin has been applied. Studies have been made of the consequences which attend a lack of vitamins in the diet; and much effort is now being expended in ascertaining to what extent, if at all, certain disorders of nutrition are attributable to a deficiency in vitamins.[2] Although many important properties of these essential food factors have been described, the attempts to ascertain their chemical identity have thus far failed. The fact that an antineuritic substance contained in yeast extracts can be absorbed by preparations of fullers' earth and thus in a sense be isolated from the medium containing it gave hope that the "active principle" might readily be isolated. In this way a purin compound, adenin, was identified, but it has proved to be inactive. Presumably the adenin is associated with the antineuritic factor only in yeast, just as nicotinic acid has been shown to be associated with it in the antineuritic extract of rice polishings.[3] Both com-

pounds, when thoroughly purified, become inactive. How, then, do the vitamins exert their functions? Conjectures have not been wanting. Very early in their history the vitamins were assumed to behave like enzymes—an analogy which lacks anything more than fanciful guesswork. In a recent elaborate treatise on dietotherapy,[4] the writer of the chapter on vitamins, reflecting the current uncertainty on the subject, has omitted conjecture as to their mode of action; but the editor has ventured the statement that in nutrition "they play a rôle which might be likened to that of the hormones in cellular activity or the opsonins and other antibodies in the infections." Attention has been directed in THE JOURNAL[5] to the lack of foundation for the once-asserted belief[6] that vitamins (or at any rate the antineuritic substances) play some part in carbohydrate metabolism. In an experimental study on rats—the classic animals in research of this type—Drummond[7] of the Cancer Hospital Research Institute, London, has found that the nitrogenous metabolism during diets deficient in the water-soluble dietary accessory substance shows no apparent deviation from the normal with the exception of an occasional creatinuria. This abnormality, however, is observed whenever there is a wasting of musculature, such as occurs as the result of the low intake of food in animals on a deficient diet.

It has been suggested, in view of the lowered food consumption observed when the water-soluble vitamin is lacking,[8] that the latter influences the appetite in some way. Drummond noted that an increased food consumption may be brought about by the addition of flavoring agents, such as meat extract, to the synthetic diets; but unless the additions contain vitamin, no growth results. The amount of growth is, within certain limits, proportional to the amount of accessory substance added, provided the diet is adequate in other respects. Such facts make it clear that vitamins are something more than mere carminatives that stimulate the appetite. Any promotion of the latter is more likely the outcome, as Osborne and Mendel have suggested, of the improved condition of the individual when vitamins are available in the diet. The cause of the fatal decline that inevitably follows a deficiency of vitamin has not yet been ascertained. It appears, however, that age plays a part in the rapidity with which symptoms of decline intervene. In older subjects, in whom maintenance rather than growth is concerned, a restriction can be borne far better than in the young.

Current Comment

THE MEDICAL PROFESSION AFTER THE WAR

In April, 1917, our country called on the medical profession for volunteers for medical service. The response was both prompt and generous. Again and again the call came, and each time met similar prompt and generous response. Some 35,000 physicians have responded to these calls and are serving in the Army or in the Navy. In addition, about 25,000 physicians have given freely of their time and labor to work on Selective Service Boards, thus making possible that efficient, physically fit machine—the National Army.

◆

It is too soon—the world, victorious and vanquished, too unsettled—to say what is coming and what is to be done. It is an hour in which nations are being made, unmade and remade. We hear, we talk, we read of reconstruction. The reconstruction problems are, in the main, twofold: one, the salvaging of mutilated humanity; the other, the reconstruction of devastated cities, towns and villages. The former, the salvaging of the heroic remnants of war-worn men, is the more important. Our reconstruction problem as applied to the physical reconstruction of the disabled soldiers is certain not to be the gigantic task that it would have been had the war continued for a long period of time. There will, of course, be much to do in this regard; but this work is in competent hands and well provided for. Our reconstruction problem as it applies to the returning of more than 30,000 military physicians to civilian life is again not a problem of magnitude. The physician before he went to war was, in most instances, a man of home and family, and in most instances home, family, his professional confrères and the community wait to welcome him with honors.

◆

However, our reconstruction problem as it concerns the relation of the physician to the great social problems that are to arise "after the war," is a problem of magnitude. One's senses are startled by phrases in the modern writings on social and economic subjects. One hears of "equalization of risk and return," of "conscription of wealth," of "health insurance," of "national ownership," of "state medicine," of a "league of nations," "international medical alliances," and similar conceptions. With these, and as a part of these, will be new problems of the relation of physicians to each other and to the public. Physicians will have as much influence as any other class in the weaving of the new social fabric. It is well to realize this and to appreciate the need of closer knitting together of the profession itself—of stronger organization—so that we may face these problems with the strength of many minds united. Thus the medical profession may be able, not only to secure the rights and recognition it merits, but also to have that real influence necessary for the best interests of the public health in the new order of things. The medical profession has served, it serves and it will continue to serve when called on, but in its altruism must not forget that the profession will have to guard its own rights and prerogatives if they are to be guarded at all.

CORN OIL AS FOOD

Elsewhere in this issue of The Journal[1] are recorded the results of an investigation, conducted in the Laboratory of Physiological Chemistry at the University of Iowa, on the digestibility by dogs of corn oil, prepared from the germ of maize, in comparison with the utilization of lard and the now widely used cottonseed for which it is chiefly substituted. The results clearly indicate that all of these fats, used in similar amounts, are essentially comparable as regards their digestibility. There is no reason to assume that the findings are not equally applicable to man. The average figures for the fat absorbed—corn oil, 98.9 per cent., cottonseed oil, 98.8 per cent., and lard, 97.8 per cent.—leave little to be desired from the alimentary standpoint. These data are in accord with the recent experiments of Holmes[2] of the United States Department of Agriculture indicating the excellent utilization, by man, of a not inconsiderable number of fats and oils of vegetable origin, some of which are as yet little known as dietary possibilities. In commenting on them, The Journal pointed out an important fact which must at present be kept clearly and prominently in mind whenever the modern "substitutive fats" are under consideration. Some animal fats, notably milk fats, contain those little understood but very important properties designated as vitamins, without which the organism ordinarily fails to grow or recover from nutritive injury as it should. Since these are not found in most vegetable oils, we must not fail, in the present stage of knowledge, to provide children and invalids with some suitable vitamin-containing animal fats, preferably perhaps from milk. Digestibility is only one factor, though a highly important one, in the nutrient possibilities of foods.

THE MATERIAL LOST IN MENSTRUATION

Although it is usually stated that the amount of blood lost at each menstrual period varies between 100 and 300 gm., there have been few accurate data available regarding the actual losses of body components incident to this physiologic change. Definite information is afforded by recent observations at the Nutrition Laboratory of Teachers College, Columbia University.[3] In periods lasting from four to five days the highest observed losses through the menstrual flow were: of nitrogen, 3.4 gm.; phosphorus, 0.06 gm.; calcium, 0.02 gm.; iron, 0.04 gm. In comparison with the normal daily metabolism, losses of this degree are comparatively insignificant except in the case of iron. The output of nitrogen in the flow represents not more than 0.1 gm., equivalent to about 6 gm. of protein per day for the month. The losses of calcium and phosphorus are smaller than the chance variations in the usual output from day to day. If the daily requirement of iron by the adult is placed at from 0.010 to 0.015 gm., it is possible that the loss of iron through the menstrual flow is sufficient to suggest consideration of it in connection with the selection of the daily diet. At any rate, the iron output offers the only obvious indication of significant loss. The outcome of the analyses is, as the investigators themselves recognize, that there is no pronounced periodicity in the output of phosphorus and calcium, and that the amounts of these elements lost in menstruation are not sufficient to make the nutritive requirements of women for these elements materially different from those of men of the same weight.

ARCHIVES OF NEUROLOGY AND PSYCHIATRY

At the session of the American Medical Association last June, a petition signed by a large number of the leading neurologists and psychiatrists of the United States and Canada was presented to the Board of Trustees, asking that the Association publish a journal to be devoted to nervous and mental diseases, on a plan similar to that on which the *Archives of Internal Medicine* and the *American Journal of Diseases of Children* are published. The board took the matter under advisement until its October meeting, at which time it acted favorably on the petition, and authorized the publication of such a journal. The journal will be known as the *Archives of Neurology and Psychiatry*. The following were appointed as the editorial board:

Dr. Pearce Bailey, New York, adjunct professor and assistant professor of neurology at Columbia University College of Physicians and Surgeons, New York.

Dr. Augustus Hoch, now of Montecito, Calif., formerly professor of clinical medicine, department of psychopathology at Cornell University Medical College.

Dr. Hugh T. Patrick, Chicago, clinical professor of nervous and mental diseases, Northwestern University Medical School.

Dr. E. E. Southard, Boston, professor of neurology, Medical School of Harvard University.

Dr. Frederick Tilney, New York, professor of neurology, Columbia University College of Physicians and Surgeons, New York.

Dr. T. H. Weisenburg, Philadelphia, professor of neuropathology and clinical neurology, University of Pennsylvania School of Medicine.

The aim of all connected with the new journal is to make it representative of the best American product in the realm of nervous and mental diseases—the best in things immediately practical as well as scientific. The press of the American Medical Association is today thoroughly equipped, and thus is prepared to produce journals such as the one under discussion in a manner satisfactory to the most critical, and at the same time economically. It is unnecessary to say that the publication of these special journals is undertaken, not with the idea of financial profit, but solely for the purpose of advancing scientific medicine in the United States.

PICRIC ACID INTOXICATION AND JAUNDICE

Picric acid (trinitrophenol), which has long been used in the manufacture of certain explosives, is recognized as the cause of occasional cases of industrial poisoning. It enters the body in the form of dust, by inhalation. Skin affections, yellow pigmentation of the epidermis and conjunctiva, and digestive disturbances have been attributed to the poison. Although picric acid has been replaced in the munitions industry to a considerable extent by the now familiar T. N. T., trinitrotoluene, the foreign war time medical literature shows that intoxication with the former has gained an unexpected prominence. This is partly due to the fact that picric acid has been used by malingerers in the attempt to avoid military service. When from 30 to 90 centigrams, that is, up to about 15 grains, of this yellow compound are taken, vomiting and diarrhea may ensue and thus remove a considerable part of the poison from the alimentary tract. If sufficient is absorbed, a coloration of the skin and sclera will ensue. This may be due to picric acid itself or to its reduction product, picramic acid, according to Malmejac and Lioust,[1] who have observed many cases. The coloration is frequently accompanied further by symptoms of true jaundice of hepatic origin as a complication of the poisoning. In that event, bile pigments and biliary acids may appear in the urine along with excreted picric acid and its derivatives. It therefore becomes imperative to examine the urine for the latter in order to permit a correct diagnosis.

Medical Mobilization and the War

Honors to Major-Gen. William C. Gorgas

Major-Gen. William C. Gorgas has been notified that the decoration of "the Grand Officer of the Order of the Crown of Italy" has recently been conferred on him.

On October 26, Secretary of War Baker, wrote the following letter to General Gorgas:

October 28, 1918.

My Dear General Gorgas:

Your official term as Surgeon-General of the Army having expired, I beg leave to express to you the appreciation of the Army and the country of the distinguished services which you have rendered during your long and brilliant career as a medical officer. Even the gracious modesty which is a part of your habit of thought cannot keep you from realizing that your career has been one of brilliant distinction, and that the Medical Department of the Army has profited from your services, as it has been honored by your deservedly high reputation. The operation of law has terminated your period of active service, except for the emergency work which you are now doing under my direction, but it will be a source of satisfaction to me and a comfort to the people of the country to realize that your interest will continue in the Army and in the great scientific researches in which your life has been engaged.

If I may add a personal word to this note, I beg you to accept my grateful acknowledgement of the cordial and helpful relations which have existed between us officially, and to thank you for the many personal courtesies and kindnesses which I have received from you during our most happy association.

I am placing a copy of this letter in the hands of the Adjutant General in order that it may become a part of your record in the department, and may there remain as an evidence of the complete success with which you as a soldier and a doctor have through long years and under varying and difficult conditions served your country.

Cordially yours,
Newton D. Baker,
Secretary of War.

Bureau of Medical Research and Intelligence for Red Cross in Paris

Among its other activities the American Red Cross in France has established a Bureau of Medical Research and Intelligence Department, of which Lieut.-Col. Alexander S. Lambert is the chief. The individual divisions are: Medical Library, Medical Publications, Medical Research and Medical Intelligence bureaus. The department undertakes to supply the field, camp and evacuation hospitals with medical books and journals as also to reply to individual requests as to most recent developments in war medicine and surgery. For the latter, the Medical Intelligence Bureau, of which Major Thomas H. Halsted is chief, is occupied specially with looking up literature, reports of commissions, etc. It responds at once to all requests for information on medical and allied subjects asked for by any medical member of the American Expeditionary Forces or of the Red Cross. An index is kept of all articles relating to war medicine and surgery, and also abstracts of the more important ones. Dr. Emil Mayer of New York City has been appointed representative of the United States for this bureau. Writers of original articles on war subjects are requested to send two reprints thereof as soon as possible to the Medical Intelligence Bureau, American Red Cross, 9 rue du Mont Thabour, Paris, France.

The Inter-Allies Institute for Rehabilitation of the War Disabled

The *Presse médicale* states that the permanent committee which has been appointed to centralize matters connected with the rehabilitation of disabled soldiers, comprises representatives of all the allied governments. They include Dr. Bourrillon (France), who serves as president of the committee; Dr. Mélis (Belgium), Sir Charles Nicholson (Great Britain), General Bradley (United States), L. March (France), Dr. Da Costa Ferreira (Portugal), and Agathonovitch (Serbia) as vice presidents. All these hold high military rank. An institute for research has been founded at the headquarters of the committee which is already installed at 102 rue de Bac, Paris. A review is to be issued by the committee. The editor in chief is Dr. Jean Camus, *professeur agrégé* at the Paris Faculté de médecine, with Dr. Bourrillon, the president of the committee, and Mr. C. Krug, the secretary general, as the board of directors for the publication. The work of the committee is to include the promulgation of the general principles for rehabilitation of the disabled, which each country can adapt to its own laws and customs; to group and centralize the data and the lessons learned from experience, and to apply them and aid in every way the mutilated and to extend this aid into the future after the war. By this coordination of efforts each one of the allied peoples will be able to profit by the improvements and achievements realized in any one of them.

Posthumous War Honors

The Distinguished Service Cross for extraordinary heroism in France has been posthumously awarded to Lieut. George P. Howe, M. C., U. S. Army, Boston, who was killed in action, Sept. 28, 1917, and to Lieut. John P. Rosenwald, M. C., U. S. Army, Minneapolis, on duty with the One Hundred and Fifty-First Artillery, who died, May 6, 1918.

Distinguished Service Cross Awards

The commander in general has awarded the Distinguished Service Cross to the following named officers of the Medical Department, American E. F.:

First Lieut. Frank L. Williams, Medical Corps. "For extraordinary heroism in action in Champagne, east of Rheims, July 15, 1918, and near the River Ourcq, northeast of Chateau Thierry, France, July 30, 1918. Lieut. Williams voluntarily left a dugout on the Champagne front and for more than two hours, all the time under shell fire, administered to the needs of wounded men who were lying in the open. During the advance across the River Ourcq he voluntarily remained in exposed positions under heavy shell fire, caring for and dressing the wounded until he was severely injured."

Capt. George H. Gage, Medical Corps, Infantry. "Conspicuous for his courage in the actions at Rambucourt, on March 17, 1918, and at Catigney, May 28, 1918. He gave inspiration to the officers and men of the command by his extraordinary heroism throughout the operations south of Soissons, July 18 to 22, 1918, and especially at Berzy-le G., July 21, 1918, when he accompanied the first line and attended the wounded in the open under incessant machine-gun and artillery fire."

First Lieut. Frederick W. Black, Field Hospital, Medical Department: "For extraordinary heroism in action near Soissons, France, July 18-22, 1918. He went over the top to the attack in the first wave and was wounded on the morning of the first day. Disregarding his wound, he pressed on with the attacking troops and crossed and recrossed the sector immediately behind the most advanced wave, rendering first aid to wounded and placing them in shell holes. He worked unceasingly without sleep or rest, and was again wounded on the fourth day by shell fire. Though twice wounded he steadily refused to be evacuated until the evening of the fourth day, when he was exhausted and suffering from his wounds."

---

[1] Malmejac, F., and Lioust, C.: Jaunisse picrique et ictère, Jour. de physiol., 1918, **17**, 685.

Capt. George E. McGinnis, Ambulance Company, One Hundred and Ten, and One Hundred and Third Sanitary Train. For extraordinary heroism in action at Fismette, France, August 9 to 10, 1918: "During the night of August 9, Captain McGinnis, with complete disregard of his personal safety, made a reconnaissance under fire and located a line of evacuation for ambulances from Fismette and on the morning of August 10, under shell fire, he personally repaired the bridge between Fismes and Fismette, thereby making possible the evacuation of twenty-eight wounded men."

Weekly Bulletin, American Expeditionary Forces

The following paragraphs are taken from Weekly Bulletin No. 27, Oct. 14, 1918, issued for circulation among American medical officers in France:

PNEUMONIA'S DEMAND IS COMPLETE ISOLATION

The demand in pneumonia is the complete isolation of patients from each other when of different bacterial etiology as if they were cases of measles, meningitis or diphtheria, all with similar symptoms. Pneumonia, it has been well said, is a group of diseases with certain common signs and symptoms, and never was this more obvious than under present conditions in France, where typical physical findings and symptoms before death have been found alike in individual patients and in groups of patients in whom examination of sputum and blood has shown almost pure cultures of pneumococcus of the various strains—streptococcus, influenza bacillus and meningococcus types B and C—confirmed as well by smears from lungs and blood after death in many instances. It behooves all medical officers to be on their guard against the dangers of mixing or crossing infections among patients by the least neglect of precautions such as cubicle isolation and masking of patients and attendants. In one case recently reported, Type IV pneumococcus and Type B meningococcus were found in abundance in the secretions of different parts of the respiratory tract. The comments of the commanding officer of the Army Laboratory are very much to the point and should stimulate more intensive study of cases and their respective etiology:

"On looking back over the case, there is considerable regret that (*a*) specimens of sputum were not examined at more frequent intervals during the course of the disease; and (*b*) that at the autopsy, smears and cultures were not obtained at varying levels down the entire respiratory tract."

This case is of chief interest from an epidemiologic standpoint: Because, if the meningococcus is frequently associated with the pneumococcus (or other organisms), in cases of pneumonia and bronchopneumonia, aside from its possibilities of being the causative agent of the condition, there arises the important possibility of the wide dissemination of the meningococcus, at the onset of the disease, by coughing and expectoration; this would be especially true in cases of bronchopneumonia, due to the more gradual onset.

Associated with this case may be mentioned a sharp outbreak of influenza-bronchopneumonia, occurring in an organization of 329 men. There were sixty-eight cases of this condition with five deaths within ten days. At the termination of this epidemic of influenza-bronchopneumonia, a case of epidemic cerebrospinal meningitis (Type B, Pasteur) developed in this organization; twenty-nine close contacts with this case of meningitis were cultured (nasopharynx), with 50 per cent. positive carriers, of whom 80 per cent. were subsequently shown to be carriers of the meningococcus (Type B, Pasteur). This percentage of positive carriers is considerable in excess of the percentage of positive carriers among contacts with cases of meningitis, not associated with coincident respiratory disease, as determined at this laboratory."

FURTHER EVIDENCE OF DISTRIBUTION OF PATHOGENIC BACTERIA

Further evidence of the distribution of the various pathogenic bacteria in pneumonia cases coming to necropsy is found in the following summary of a report from the central laboratory:

"The bacteriologic examinations of lungs at necropsies in thirty cases of pneumonia at Base Hospital No. 17 during September, 1918, showed Pfeiffer bacillus in twelve (or 40 per cent.), pneumococcus in thirteen (or 43 per cent.), streptococcus in ten (or 33 per cent.). Considering the difficulties attending the isolation of the influenza bacillus and the possibility of its being absent from the lung at necropsy, although actually an important agent in the disease, the results indicate that this organism has been of primary importance in this group of cases. From other reports of epidemics in various parts of the advance section it is considered that the above findings are characteristic of the present epidemic."

CHANGE IN MEDICAL LEADERSHIP IN A. E. F.

On October 12 Major-Gen. Merritte W. Ireland left the A. E. F. for his new responsibilities as Surgeon-General, U. S. Army.

Col. Walter D. McCaw, appointed chief surgeon of the A. E. F., assumed the duties of the position vacated by General Ireland's departure.

◆

The following paragraphs are taken from Weekly Bulletin No. 28, Oct. 21, 1918, issued for circulation among American medical officers in France:

INFLUENZA, PNEUMONIA, MENINGITIS

During the past two months a second wave of severe influenza infection has swept over France and has spread to all the countries of Europe in about equal force. In the United States the onset of the epidemic was, as is usually the case with pandemics of influenza, about three weeks later than in London and Paris. The first and rather benign phase of the infection, it will be remembered began in the middle of April and had largely disappeared in the American Expeditionary Forces by the end of July. The second phase which has not yet reached its maximum incidence has been characterized by a much higher percentage of initially severe cases and particularly of pulmonary complications. Coming at the time of rainy and changeable weather this new invasion of infectious colds and coughs has been accompanied by a constantly increasing number of pneumonias. New replacement draft detachments arriving with each convoy have added the heaviest percentage of infected men per strength and have shown the highest percentage of complicating pneumonias. It has been a usual observation that when infections of the upper respiratory tract prevail, the incidence of meningitis in the community increases soon after and this rule prevails at present. An increasing severity of the pneumonia is commonly found when the disease is permitted to pass rapidly through successive hosts.

Week Ending	Cases Influenza	Cases Acute Bronch.	Cases Bronch. Pneu.	Cases Lobar Pneu.	Cases Meningitis	Deaths among Pneumonias
Sept. 13	3,066	495	78	401	21	14.5%
Sept. 20	4,279	476	101	376	18	29.3%
Sept. 27	3,921	524	154	427	47	31.9%
Oct. 4	9,285	988	364	671	88	34.9%
Oct. 11	5,794	890	194	401	134	45.3%

It is known that not less than 200,000 cases of influenza were reported during the past week among the troops in the camps in the United States. It has been officially reported that 80 to 90 per cent. of the mobilized army of Switzerland was affected soon after the introduction of the infection by prisoners exchanged through Switzerland from Germany. From official information from Portugal it appears that the influenza infection is no less severe there than in the American Expeditionary Forces, and the pneumonia is of as fatal a type.

The influenza and pneumonia now prevalent among French civil and military population is at least as severe as in the troops of the American Expeditionary Forces. The areas of heaviest infection of influenza, pneumonia and meningitis in the American Expeditionary Forces are the base ports, the depot divisions and such training areas in both service of supplies and advance zones as have received replacements or new organizations still including men exposed to the massive infection which has prevailed on the transports and on troop trains.

Substantial relief is to be expected soon from the frequently recurring infections introduced through base ports by incoming troops by the following improvements:

(*a*) Careful exclusion of men with colds, coughs and fever from transports at ports of embarkation.

(*b*) Equipment of all troops prior to embarking with three blankets, an overcoat, and winter weight woolen underclothing.

(*c*) Reduction of troops carried on transports to 80 per cent. of berth capacity.

(*d*) Increase of hospitalization capacity on transports to 4 per cent. of troops.

(*e*) Shelter ready and standing for troops on arrival at base ports, with provision for permanent kitchen and mess service for arriving troops.

(*f*) Period of not less than four days with no heavy duty on debarking.

(*g*) Medical supervision of troops on troop trains.

(*h*) Gradual hardening and acclimatization process at depot divisions, with isolation so far as practicable of new arrivals from earlier arrivals or permanent troops until infection has been eliminated.

(i) Increase in the floor space per capita to be provided wherever practicable up to 40 square feet per man.

(j) Separation of adjacent bunks by permanent board or shelter half partitions.

It will take continued concerted effort by all medical officers in the application of all measures of local sanitation and supervision of the personal hygiene of the men to avoid further extension of influenza with its complicating pneumonias and often coincident meningitis. Men's bodies must be kept warm. Their clothing must be dried at least once a day.

Sufficient blankets and drying rooms accessible to every one, especially in the regions immediately back of the fighting front are indispensable for prevention of pneumonia. In the service of supplies and in areas occupied by troops in training or reserve the problem is largely one of personal contact and crowding; among the troops at the front it is a question of fatigue and exposure; determination to remedy both will go far to save lives.

A report from the First Army Corps indicates that pneumonia is not epidemic, though prevalent there; that influenza bacillus and pneumococcus are the usual infecting bacteria; that incomplete clothing equipment and sleeping in cold and wet are the chief contributing causes.

EPIDEMIC DISEASE REVIEW FOR THE WEEK

Reports from the American Expeditionary Forces for both influenza and pneumonia show a reduction in the number of new cases of these diseases. A similar reduction in new cases has been reported by the French authorities from certain areas, notably the District of Paris and the Arrondisoment of Tours, these reports including the conditions in the civil as well as in the French military population. The convoys which have arrived in the past week have shown a decidedly lower death rate and incidence of influenza and pneumonia en route than has been the case for the previous three weeks. The death rate from pneumonia has risen in the past five weeks from 14.5 to 45.4 per cent. of cases.

Meningitis has fallen from 167 cases reported last week to 147 this week. Of these sixty-five were reported from base ports among the sick hospitalized on arrival of transports and thirty-six more occurred in the depot divisions, training areas, and even in troops in the advance section among contingents which had been in France less than two weeks and had been exposed to heavy infecting during ship and rail transportation. The forty-eight cases of meningitis not thus accounted for as new importations in the American Expeditionary Forces were from widely scattered points and were not grouped in epidemic foci.

Of the 163 cases of measles 139 were among recently arriving troops and were detected at base ports and at depot divisions. Of the thirty-nine reported cases of dysentery nineteen were from one hospital in the advance section and the origin is thought to have been exposure and unsuitable food rather than an infection with specific dysentery organisms.

The diphtheria is chiefly chargeable to combat troops in the advance section (forty-one of seventy-eight cases). The cases reported from the intermediate section are chiefly among the recently evacuated men in base hospitals and among hospital personnel in the base hospitals.

The eight cases of typhoid fever, all from Novors, are part of a local outbreak in which thirty other cases have occurred in the French population. Contaminated food served by unrecognized carriers or cases in the public eating places is supposed to be responsible for this outbreak.

COMMISSIONS OFFERED AND ORDERS TO DUTY ON ACCEPTANCE

Alabama

To Camp Jackson, S. C., base hospital, for instruction, Capt. E. M. PRINCE, Birmingham.

To Fort Oglethorpe for instruction, Lieuts. C. C. BOX, Ashford; E. O'CONNELL, Birmingham; B. T. BRIDGES, Black; J. T. PATTILO, Shawmut; I. C. BATES, Taylor; N. S. GAY, Whistler.

Arizona

To Camp Cody, N. M., base hospital, Capt. R. R. BROWNFIELD, Phoenix.

To Camp Kearney, Calif., Lieut. C. I. HUGHES, Phoenix. Base hospital, for instruction, Lieut. A. B. CARMICHAEL, Prescott.

Arkansas

To Camp Pike, Ark., Lieut. W. H. OWENS, Turrell.

To Fort Riley for instruction, Lieuts. R. C. KENNERLY, Artisian; W. M. CARNER, Bodcaw; G. F. McLEOD, Magnolia; N. HORTON, Plumerville; W. S. EMBREY, Texarkana.

California

To Camp Cody, N. M., base hospital, for instruction, Capt. I. W. JONES, Lieut. W. H. BROWNFIELD, Los Angeles.

To Camp Fremont, Calif., Lieut. E. H. NEWBOLD, Oroville. Base hospital, for instruction, Capt. C. O. FALK, Eureka.

To Camp Kearney, Calif., Capts. G. H. HASTINGS, Los Angeles; E. S. BLAIR, San Bernardino; Lieuts. R. M. O'NEAL, Bishop; F. A. EDWARDS, Los Angeles; J. F. KERGAN, Oakland. Base hospital, Capt. H. BARKAN, San Francisco. Base hospital, for instruction, Capts. C. A. DOZIER, C. J. TEASS, San Francisco; Lieut. R. S. LEACHMAN, Vallejo.

To Camp Lewis, Wash., Capt. D. R. SMITH, Mendocino; Lieut. H. D. BRUSCO, San Francisco.

To Fort Oglethorpe for instruction, Capts. W. S. JOHNSON, Los Angeles; J. R. FEARN, Oakland; V. E. PUTNAM, San Francisco; F. W. REYNOLDS, San Padro; Lieut. G. R. LUTON, Santa Barbara.

To Fort Riley for instruction, Capt. R. J. NICHOLLS, San Francisco; Lieut. W. E. BIXBY, Sebastopol.

To Mineola, N. Y., Hazelhurst Field, for instruction, Capt. P. DOLMAN, San Francisco.

To New York, Neurological Institute, for instruction, Capt. H. M. WEGEFORTH, San Diego.

To report to the commanding general, Western Department, Capts. L. R. DUPUICH, A. M. GREGORY, Oakland; J. A. SHRECK, Redlands; R. R. BULLOCK, W. W. WYMORE, San Francisco; H. E. PIPER, Santa Cruz; Lieuts. N. BROWN, Jr., Bakersfield; C. W. HUTCHISON, Coalinga; J. T. CHRISTIAN, Galt; J. M. CONERTY, Los Angeles; C. L. EMMONS, Ontario; H. I. BLOCH, San Francisco; F. E. HULL, Tipton; W. A. JOYCE, Woodland.

Canal Zone

To Fort Oglethorpe for instruction, Capt. W. E. HUBBARD, Ancon.

To report to the comanding general, Panama Canal Department, Lieut. W. W. BRAITHWAITE, Ancon.

Colorado

To Camp Cody, N. M., Capt. J. W. FOLEY, Denver.

To Fort Oglethorpe for instruction, Capt. E. W. RAGSDALE, LaJunta; Lieut. F. M. HELLER, Pueblo.

To Fort Riley for instruction, Capt. J. B. HARTWELL, Colorado Springs; Lieuts. G. A. ASHBAUGH, Central City; M. D. CURRIGAN, Denver.

Connecticut

To Camp Devens, Mass., Lieut. F. T. FITCH, East Hampton.

To Camp Dix, N. J., Lieut. A. F. HEWITT, Stamford.

To Fort Oglethorpe for instruction, Capts. F. M. DICKINSON, Rockville; C. E. SIMONDS, Willimantic; E. R. KELSEY, Winstead; Lieuts. L. A. HA OOK, East Haddam; E. C. KIERNAN, New North Haven.

To Hoboken, N. J., Lieut. R. S. DAY, New Milford.

To report to the commanding general, Northeastern Department, Capt. B. E. BOSTWICK, New Milford.

District of Columbia

To Fort Oglethorpe for instruction, Capt. N. P. BARNES, Washington; Lieut. A. D. BUTZ, Washington.

To Newport News, Va., Capt. P. B. JOHNSON, Washington.

To Washington, D. C., Major J. CONSTAS, Washington.

Florida

To Camp Joseph E. Johnston, Fla., Capt. W. M. STINSON, Jacksonville.

To Fort Oglethorpe for instruction, Capt. H. E. PALMER, Tallahassee; Lieuts. H. E. CLINE, Haines City; G. E. BECKMAN, Jacksonville; E. G. PEEK, Ocala; I. J. BELCHER, Tarpon Springs.

Georgia

To Camp Greene, N. C., base hospital, Capt. G. D. AYER, Atlanta.

To Camp Jackson, S. C., base hospital, for instruction, Capt. T. J. COLLIER, Atlanta.

To F ruction, Lieuts. W. D. JENNINGS, Jr., Augusta Metasville; H. B. NUNNALLY, Monroe; C. W.

Idaho

To Denver, Colo., Capt. A. R. HULL, Nampa.

To Fort Riley for instruction, Capt. C. R. SCOTT, Twin Falls; Lieut. W. T. DRYSDALE, New Plymouth.

To report to the commanding general, Western Department, Lieut. C. F. HANMER, Salmon.

Illinois

To Army Medical School, Lieut. D. A. HUMISTON, Oak Park.

To Camp Custer, Mich., Lieut. G. B. MATHISEN, Chicago. Base hospital, Capts. J. W. CLARK, M. H. WORTHINGTON, Chicago; E. H. PARRY, Galesburg.

To Camp Grant, Ill., base hospital, Capt. B. HASELTINE, Chicago. Base hospital, for instruction, Capt. A. J. ROBERTS, Ottawa.

To Camp Pike, Ark., Capt. T. F. CONROY, Lieut. H. A. KRAUS, Chicago.

To Camp Sherman, Ohio, base hospital, for instruction, Capt. W. C. SMITH, Chicago.

To Camp Wheeler, Ga., base hospital, for instruction, Lieut. J. W. MILLER, Chicago.

To Camp Zachary Taylor, Ky., base hospital, Lieut. J. H. FRAZER, Chicago.

To Cape May, N. J., base hospital, Lieut. S. J. TAUB, Chicago.

To Fort Oglethorpe for instruction, Major R. C. BOURLAND, Rockford; Capts. F. W. BRIAN, Bloomington; R. R. DUFF, P. GRONNERUD, E. J. HOGLUND, L. J. ISAACS, A. E. PRICE, Chicago; A. F. MOORE, Dixon; W. J. CARTER, Mattoon; C. L. CARLTON, Moline; E. A. WALSH, Springfield; Lieuts. D. SCHOTT, Buckley; L. L. IRWIN, Bloomington; E. H. ANDERSON, F. R. BUTTERFIELD, J. A. COUSINS, L. J. P. DE ALARID, W. G. EPSTEIN, R. R. HARRINGTON, D. L. HYDE, V. N. LAMARRE, J. W. McLAUGHLIN, A. N. OYEN, H. L. THOMPSON, V. K. TOMHAGEN, Chicago; E. C. PARK, Jr., Flora; J. H. WEDIG, Granite City; J. I. MERSHON, Keithsburg; F. M. HAGANS, Lincoln;

D. G. WELLS, McHenry; J. L. SNAVELY, Sterling; C. O. HIGHSMITH, West Union.

To Fort Riley, Lieuts. J. J. EGAN, Chicago; R. E. UTLEY, Oak Park. For instruction, Lieuts. G. C. BUNTIN, Benton; B. AUGUSTUS, J. E. BROOKS, T. E. DOYLE, W. Z. FELSHER, J. H. HUTTON, W. J. MULHOLLAND, J. M. VITULLO, Chicago; H. H. HEUCK, Sigel; L. V. BOYNTON, Vermont.

To New Haven, Conn, Capt. H. H. BAY, Lieut. E. B. FREILICH, Chicago.

To report to the commanding general, Central Department, Capt. G. E. PUMPHREY, Carthage; Lieuts. T. GRIFFITHS, Chicago; H. A. BARKEY, Elmhurst.

Indiana

To Camp Beauregard, La., base hospital, for instruction, Capt. G. S. GREENE, Gary.

To Camp Custer, Mich., base hospital, Capt. E. H. KATTERHENRY, Indianapolis.

To Camp Dodge, Iowa, base hospital, Lieut. J. H. BULL, Indianapolis.

To Camp Pike, Ark., Lieut. J. R. CROWDER, Sullivan.

To Camp Shelby, Miss., Capt. L. M. GENTLE, Richmond.

To Camp Zachary Taylor, Ky., Lieut. C. W. COREY, Hartford City. Base hospital, Capt. H. K. LANGDON, Indianapolis.

To Colonia, N. J., Lieut. C. A. BALLARD, Logansport.

To Fort Oglethorpe for instruction, Capts. H. A. DUEMLING, Fort Wayne; B. A. BROWN, Indianapolis; J. W. BAXTER, C. E. BRISCOE, New Albany; W. L. OWEN, South Bend; C. L. BOYD, Vincennes; A. I. DONALDSON, Washington; Lieuts. E. CARTER, Bringhurst; C. R. GRAHAM, Bryant; G. R. FINCH, Center Point; I. E. BOOHER, Connersville; C. R. BASSLER, Elkhart; J. BENZ, Hardinsburg; T. O. MORRIS, Hobbs; J. W. CANADAY, G. W. KOHLSTAEDT, C. W. ROLLER, Indianapolis; A. A. REED, Jeffersonville; F. S. CUTHBERT, Kingman; O. D. HUTTO, Kokomo; B. M. HUTCHINSON, Mishawaka; J. E. NIXON, Portland; J. W. RICKER, Terre Haute.

To Fort Riley for instruction, Lieuts. G. F. SMITH, Lawrenceburg; V. L. HODGES, St. Paul; N. A. BAKER, Valparaiso; S. C. WAGNER, Wakarusa.

To New Haven, Conn., Capts. E. A. CRULL, Fort Wayne; A. HENRY, Indianapolis. Yale Army Laboratory School, Lieut. J. E. ROGERS, Marion.

To report to the commanding general, Central Department, Lieut. B. F. CHAMBERS, Lyons.

Iowa

To Camp Dodge, Iowa, base hospital, Capt. L. M. COFFEY, Keokuk.

To Camp Grant, Ill., base hospital, Capt. E. A. CANTONWINE, Dubuque.

To Camp Pike, Ark., Lieut. T. A. HOBSON, Parkersburg.

To Fort Oglethorpe for instruction, Capt. M. B. DUNNING, Conway.

To Fort Riley for instruction, Capts. A. B. DEERING, Boone; J. P. REDMOND, Dysart; H. C. HULL, Washington; Lieuts. R. A. BECKER, Anita; W. A. COOPER, Bayard; F. S. LEONARD, Cascade; T. J. DORSEY, Clare; P. G. INGERSOLL, Dunlap; C. W. PATTON, Laurel; F. W. NEWELL, Ottumwa.

To New Haven, Conn., Yale Army Laboratory School, for instruction, Capt. C. B. LUGINBUHL, Des Moines.

Kansas

To Camp Custer, Mich., base hospital, for instruction, Capt. J. L. EVANS, Wichita.

To Camp Pike, Ark., base hospital, for instruction, Lieut. A. W. FEGTLY, Douglass.

To Fort Oglethorpe for instruction, Lieut. O. O. BARKER, Muscotah.

To Fort Riley for instruction, Lieuts. J. L. WENTWORTH, Arkansas City; F. H. BELL, Baldwin; W. L. DAVIS, Corning; J. W. GRAHAM, Highland; E. M. MIERS, Salina; D. L. STEWART, Scranton; G. D. M. LAMBDIN, Sedan; W. H. POPE, Selden; B. ANDERSON, Victoria.

Kentucky

To Camp Zachary Taylor, Ky., Capt. S. S. PRATHER, Louisville.

Acting Asst. Surg. J. M. BIEDLER, proceed to Richmond, Va., for organization of medical and sanitary work at the Government loading plant.

Acting Asst. Surg. RICHARD T. LEADER, relieved at Charlotte, N. C., proceed to Lincoln, Neb., to assume charge of venereal control work.

Acting Asst. Surg. C. W. WOOD, proceed to Burlington, Vt., relative to the inauguration of venereal disease control measures.

Asst. Sanitary Engr. SIDNEY BOWNE, relieved at Millington, Tenn., proceed to Charleston, S. C., for duty in extra-cantonment sanitation.

Asst. Sanitary Engr. M. G. PARSONS, relieved at West Point, Miss., proceed to Columbus, Ga., for duty in extra-cantonment zone sanitation.

Asst. Sanitary Engr. F. D. MESSENGER, proceed when convenient, to Brownsville, Texas, to investigate the public health value of contemplated improvements.

Asst. Sanitary Engr. FRANK R. SHAW, proceed to New Orleans, La., for conference relative to influenza control.

Chief Sanitary Insp. HARRY S. LUCAS, relieved from duty in the District of Columbia. Proceed to Florence, Ala., for duty in extra-cantonment sanitation.

Scientific Asst. W. H. PRICE, [illegible] Anniston, Ala., proceed to Washington, D. C., for duty in [illegible]

Asst. Director Educational Wor[illegible] New York City for conference relative to venereal disease control.

Asst. Director Educational Work DAVID ROBINSON, proceed to necessary points in the States of California, Oregon, Washington, Montana, Wyoming and Idaho for conference relative to instructions to drafted men to be carried out under government supervision.

Regional Field Director HARRY R. MINOR, proceed to necessary points in the states of Virginia, West Virginia, South Carolina, North Carolina and Georgia for conference relative to instructions to drafted men, to be carried out under government supervision.

Regional Field Director A. G. SPAULDING, proceed to necessary points in the states of Texas, Nebraska and Oklahoma for conference relative to instructions to drafted men, to be carried out under government supervision.

Association News

SUPPLEMENTARY REPORT OF THE WAR COMMITTEE

At the meeting of the Board of Trustees, held October 25, the War Committee submitted the following supplementary report covering the work done since the last annual session. The Board of Trustees received and directed that it be published in THE JOURNAL.

To the Board of Trustees of the American Medical Association:

This report of your War Committee is supplementary to that which the committee submitted to the House of Delegates at its meeting held in Chicago, June last. We repeat what was said at that time that the profession has responded for war service in a manner that has received universal favorable comment, and your committee is gratified to record the part which this Association has taken in this mobilization of the medical profession for war.

The Association's records show that more than 200,000 blank forms for making application for commission in the Medical Reserve Corps have been printed by the Association and circulated among physicians, and as a result upward of 30,000 applicants have been commissioned in the Army. In addition, more than 3,000 have been commissioned in the Navy.

The appeal of the Surgeon-General of April 3, 1918, was published in THE JOURNAL on April 13. This was more effective than any community propaganda could possibly have been. Since our last (June) report, according to the Association's record, the applications for commission in the Medical Corps were: June, 2,416; July, 2,841; August, 3,814; September, 4,171, and to October 24, 2,507; a total of 15,809 in four and a half months.

The American Medical Association has been the center of information to physicians. The replies to individual inquiries have involved several departments, and letters to individual physicians have averaged over 100 each week. In addition, since June 1, more than 5,000 pamphlets covering information pertaining to entrance into the Medical Corps have been distributed in response to individual requests. The expense incident to all this, including printing, postage, and other items, have been borne by the Association.

The American Medical Association has supplied state and county organizations with detailed information concerning physicians in their own communities who were available for civil and industrial practice, and has cooperated with its branch organizations in endeavoring to provide the services of additional physicians where the needs of a locality could not be met by physicians still active in these communities.

Early in the year, on the suggestion of the officers of the Association, the Provost Marshal-General requested the Surgeon-General to assign a medical officer to the office of the Provost Marshal-General in order that this medical officer might act as an adviser on the medical features of the Selective Service Regulations. Col. Frank Billings was assigned to this post.

As an outgrowth from this beginning, a medical division for the Provost Marshal-General's Office was created on August 1, which, at the present time, has a personnel of four medical officers and five enlisted men and clerks. The function of this medical division relates to the selection and induction of registrants together with the statistical details arising therefrom. This medical division in the Provost Marshal-General's Office has brought about more intimate relations between this office and that of the Surgeon-General of the Army. Through the coordination thus made possible, the physical examinations of registrants by the Selective Service Boards and those made at the cantonments and camps are being standardized.

Your committee congratulates the Association on the service which, by virtue of the information which it has made available, it has been able to render in the solution of medical questions that have arisen in connection with the execution of the Selective Service Regulations.

Although neither the Surgeon-General of the Army, of the Navy, or of the Public Health Service, nor the Provost Marshal-General, may officially recognize any civilian organization in the mobilization of the medical profession for military service, your committee respectfully recommends that the American Medical Association continue as heretofore to render whatever aid it may to these Surgeon-Generals and to the Provost Marshal-General and that the Association continue the policy which it has constantly followed of aiding in every possible way with the individual members of the organization to determine and meet their obligations in these matters.

In this connection, the War Committee recalls the fact that the medical officers of the staffs of the Surgeon-Generals, the members of the Medical Corps of the United States Army, of the medical forces of the United States Navy, of the United States Public Health Service, of the medical division of the Provost Marshal-General's Office, and the medical section of the Advisory Commission of the Council of National Defense, are practically all members of the American Medical Association and that all commissioned medical officers of the United States Army, the United States Navy, and the United States Public Health Service, while on active duty, are also ipso facto Fellows of the American Medical Association.

Your War Committee calls attention to the fact that the Provost Marshal-General, through legally constituted provision, has assumed control of all men, including physicians, between the ages of 18 and 46 inclusive, for war service. The District Exemption Boards under the Selective Service Regulations, are empowered to place physicians of draft age in deferred classes for the protection of industries, communities, hospitals, medical schools, and public health service. These District Exemption Boards, and they alone, may for good and sufficient reasons exempt physicians of draft age from military service. In a word, all physicians under 46 years of age are under the direction of the Provost Marshal-General who, in turn, has empowered the Exemption Boards of the Selective Service System to induct physicians into military service or to detain them for civilian service as these boards deem best. At the same time, the Surgeon-Generals of the Army and Navy may commission physicians who volunteer in the Medical Corps of the Army or in the Medical Force of the Navy. Moreover, by mutual agreement with the Provost Marshal-General, these Surgeon-Generals may transfer physicians who have been inducted into the Army through the Selective Service Regulation from the line into the Medical Corps, and commission them.

Inasmuch as this is the first meeting of the Board of Trustees since June, 1918, our committee takes this opportunity to advise what position it believes the Association should take in regard to the Volunteer Medical Service Corps.

It is not a military organization, therefore its members cannot be placed under military discipline, nor can any member of the organization be forced to serve in the Army, Navy, Public Health Service or in the Office of the Provost Marshal-General. In consequence, it is not quite clear how it is to accomplish its announced object or purpose. Had the draft age not been raised to 45, or had the inactive list of the Medical Reserve Corps been continued, the organization would probably have been of assistance, provided it had been placed under military control, in solving the problem of securing a sufficient number of medical officers for the Army and Navy without seriously crippling the civilian practice.

With the increase of the draft age, a sufficient number of medical officers in the Army and Navy is now readily available, and the need of the civilian practice has become the function of the Selective Service Boards.

The Volunteer Medical Service Corps has received the approval of the President of the United States, which fact must receive due consideration. Your committee, therefore, recommends that we recognize the Volunteer Medical Service Corps as an organization in which physicians who are past military age, or whose services, because of physical or other conditions, are not available for the Army or Navy, may show their patriotism and willingness to give their services to which their qualifications entitle them.

It should be borne in mind that the government has constantly refused to draft the medical professional as a class, and has left physicians who are above the draft age, free to volunteer their services. This same freedom of action still remains to all physicians who are beyond draft age, 46 years. Membership in the Volunteer Medical Service Corps does not relieve the individual physician of his personal obligation to the country, nor does it affect his individual responsibilities to decide what his duty is regarding offering his service directly to the department of the government in which he desires to serve.

Hubert Work, Chairman,
A. R. Mitchell, Arthur D. Bevan,
Frank Billings, Geroge H. Simmons,
W. C. Phillips, Alexander R. Craig.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Baby Health Centers Opened.—The Children's Aid Committee of San Francisco announces that thirty baby health centers will be opened in the city as soon as possible after the subsidence of the epidemic of influenza.

Los Angeles Unit Leaves for France.—The Woman's Hospital Unit of Los Angeles, assigned for active work in France, left for New York. The unit is composed of ten women physicians, Drs. Etta G. Gray, Margaret M. Gilliland, Cecilia Reiche, Margaret Isaac Wilson, Maria C. Wells and Eva K. Greene, all of Los Angeles, and four other physicians, ten hospital aids, an ambulance driver and a chauffeur.

San Francisco Physicians Called Before State Board.—A number of physicians were ordered to appear before the State Board of Medical Examiners, October 22, to show why their licenses should not be revoked. Among these were Dr. William S. Card, San Francisco; Franklin P. Duncan and Charles L. Calhoun, charged with the performance of illegal operations; "Dr." Harry Ryberg, chiropodist, charged with advertising so as to give the impression that he is a physician; "Dr." C. L. Davis, an osteopath, charged with giving medicine, and Dr. David I. Hicks, charged with the performance of illegal operation and fictitious advertising.

League for Conserving Public Health.—At a conference held in Redding, recently, the Shasta County unit of the League for the Conservation of Public Health, was organized, and the following officers were elected: president, Dr. Ferdinand Stabel, Redding; vice presidents, Drs. George E. Flora, Anderson, and John P. Sandholdt, Kennett, and secretary-treasurer, Dr. Carl A. Mueller, Redding. League branches have been established and are in active operation in Santa Clara, San Mateo, Monterey, San Joaquin, Sacramento, San José, Sonoma, Stanislaus, Fresno, Alameda, San Francisco, Los Angeles, San Diego and Riverside counties.

Personal.—Dr. Ellis Harbert, Stockton, who has been seriously ill, is now believed to be out of danger.——Dr. Frank H. Pritchard, Colton, is reported to be seriously ill with influenza.—Dr. Casper L. Rinker, Madero, is said to be seriously ill with influenza.——Dr. Ray R. Dearborn, Madero, while making an emergency call sustained painful injuries by the overturning of his automobile.——Dr. George H. Galbraith, Long Beach, who has been ill with influenza, is convalescent.——Dr. Edward R. Kellogg, Los Angeles, has been reelected president of the Children's Home Society of California.——Dr. Edwin H. Crabtree, police surgeon of San Diego, has resigned to enter the United States service. ——Bail is said to have been ordered forfeited in the case of Dr. Alexander M. Lesem, San Diego, charged with violating the drug act regarding the prescribing of narcotics.——Dr. August Schmidt, Los Angeles, is said to have been held pending federal investigation on charges of having made statements to injure the sale of Liberty Loan Bonds.——Dr. Homer L. Wells, San Diego, charged with violation of the state drug act, was acquitted.

DELAWARE

Liquor Prescribing Stopped.—On complaint that Dr. Thomas O. Cooper, Wilmington, was issuing hundreds of prescriptions for liquor, Deputy Attorney-General Green and Chief of Police Blank are said to have visted his office, October 19, and warned him to cease his activities.

Personal.—Dr. Allen A. Perkins, city physician of Wilmington, has resigned to accept a position as physician to a shell plant at Port Penn.——Dr. Eli Nichols, Wilmington, who had been seriously ill with pneumonia, is reported to convalescent.——Dr. John L. Fisher is reported to be seriously ill with influenza.——Dr. Joseph B. Waples, Georgetown, has been elected physician to the Sussex County Almshouse, to succeed Dr. George E. James, who has entered the military service.

ILLINOIS

Illegal Practitioner Arrested.—Kathryn Forbrich Thumm was arrested by the Department of Registration and Education of the State of Illinois for practicing medicine without a license and was fined $25 and costs.

Rock Island Physician Liberated.—Dr. James D. Banta, Rock Island, who was arrested, tried and found guilty of violating the Harrison Narcotic Law, about six months ago, and was sentenced to five years imprisonment in the federal penitentiary, Leavenworth, Kan., was released, October 28, as it was found that he had been convicted and imprisoned under invalid acts.

Thanks for Medical Officers.—In view of the valuable assistance rendered by medical officers at Camp Grant, during the recent epidemic of influenza, Marlin H. Day, chairman of the Red Cross emergency influenza committee, Rockford, sent letters of thanks to Capts. F. D. Harrison, R. E. Jones and N. M. Johnson, M. C., U. S. Army, who were assigned to duty at the three emergency hospitals opened in Rockford in October.

Health Investigation of Working People.—The Illinois Health Insurance Commission appointed to investigate illness in working people not covered by the Workman's Compensation Act, and to make recommendations to the legislature looking toward the solution of the problems related thereto held a series of public meetings in the following cities: Chicago, November 7 to 9; Moline, November 11; Peoria, November 12; East St. Louis, November 13; Springfield, November 14; Champaign, November 15, and Danville, November 16. Labor organizations, employers of labor, representatives from the medical profession, health department officials, representatives of insurance companies and fraternal orders, social workers and others interested participated in these conferences.

IOWA

Hospital Corner Stone Laid.—The corner stone of St. Luke's Hospital, Davenport, was laid, October 2, with impressive ceremonies. The services were in charge of Bishop Morrison, Iowa City, and Rev. LeRoy M. Kauffman, Davenport, delivered the principal address. The hospital will cost about $200,000 and will contain 100 rooms for patients.

Personal.—Dr. Jay M. Crowly, Rock Rapids, is seriously ill with pneumonia following influenza.——Dr. Dennis F. Fitzpatrick, Iowa City, has been appointed local surgeon for the Rock Island System, to succeed Dr. John G. Mueller, deceased.——Dr. Edgar L. Bay and Richard F. Shahan, Eddyville, are reported to be seriouly ill with pneumonia. ——Dr. Ewen M. McEwen, Iowa City, is ill with diphtheria in the isolation hospital.——Dr. Chauncey P. Smith, Mason City, has been made chairman of the medical advisory committee for the local exemption boards, to succeed Dr. Channing E. Dakin, who has resigned to enter the military service.——Dr. Max E. Witte, Clarinda, has been reappointed superintendent of the Clarinda State Hospital.

LOUISIANA

Dowling Made Professor.—Dr. Oscar Dowling, Shreveport, president of the state board of health, has been elected adjunct professor to take charge of the course of hygiene in the School of Medicine of Tulane University, and to arrange the course of instruction for the students at Camp Martin.

New Health Board Appointments.—Governor Pleasant, October 29, announced the following appointments: as member and president of the state board of health, Dr. Oscar Dowling, Shreveport, and as members of the state board of health, Dr. Theophilus T. Tarlton, Grand Coteau, and Dr. Thomas A. Roy, Mansura, all reappointed.

MARYLAND

Health Conditions Almost Normal.—According to a statement made by Dr. John D. Blake of the health department, Baltimore came out with fewer fatalities and with less inconvenience in the recent influenza epidemic than did most of the large cities. The disease has disappeared almost entirely, there being only eight cases reported in the last twenty-four hours. A total of thirty-five persons died from all causes. This is the normal death rate in Baltimore. There were 4,664 deaths in the city from all causes during October, compared with 847 for the same month last year. The death rate per thousand of the whole population was 91.52. Lobar pneumonia, following influenza, killed 1,685, and bronchopneumonia 385. Other diseases were fatal in the following number of cases: tuberculosis, 167; heart disease, 200; diseases of babies of less than 2 years of age, 152; typhoid fever, 19; scarlet fever, 2; whooping cough, 23; diphtheria, 12; erysipelas 1; tetanus, 1; cancer, 47; epidemic meningitis, 5; apoplexy, 62; bronchitis, 26; Bright's disease, 105. The health department also reported thirty-one fatal accidents, fourteen suicides and eleven murders.

MICHIGAN

Personal.—Dr. Edward A. Runyan, health officer of Harbor Springs, has resigned, and has been succeeded by Dr. Levi W. Gardner.——Dr. Joshua G. R. Manwaring, Flint, who has been critically ill at Fort Oglethorpe with pneumonia, is reported to be improving.——Dr. Garner M. Byington, Charlotte, has been appointed a member of the state board of health and placed in charge of the newly created department of communicable diseases.——Dr. Henry M. Warren, Jonesville, has retired after more than fifty years of practice.

MINNESOTA

Postponement of Meeting.—Owing to the epidemic of influenza and the great number of physicians at present in military service, the executive council of the Southern Minnesota Medical Society announces that the society will not be convened in annual session on November 25 and 26.

Personal.—Dr. Patrick G. McGill, health commissioner of Superior, Wis., who has been working unremittingly since the first relief train from the fire-devastated region of Northern Minnesota arrived in Superior, and also in the influenza epidemic, is under treatment in a local hospital. Dr. Charles H. Mason has been appointed health commissioner during the illness of Dr. McGill.——Dr. Hibbert W. Hill, secretary of the St. Paul Public Health Association, has been appointed by the northern division of the American Red Cross to take charge of all relief work for fire and influenza patients.——Dr. Arthur E. Nichols, St. Paul, has been appointed director of school hygiene.——Dr. Herman W. Foehlich, Thief River Falls, has been appointed epidemiologist for Pennington and the surrounding counties.——Dr. Adolph E. Voges, White Bear Lake, has been elected physician of Ramsey County, to succeed Dr. Ernest W. Cowern, North St. Paul, who has entered the military service.

NEBRASKA

Hospital Corner Stone Laid.—The corner stone of the New Lutheran Hospital, Falls City, was laid recently. The building is to cost between $80,000 and $90,000.

Personal.—Dr. J. P. Connolly, Omaha, is making plans to proceed to Shanghai this month to take the position of clerk of the United State District Court of China.——Dr. Charles W. M. Poynter, Omaha, acting chief of the Nebraska University, has been appointed State Red Cross representative to act in conjunction with the state board of health during the influenza epidemic.——Dr. Irvin C. Munger, Lincoln, has been appointed physician to the State Penitentiary, to succeed Dr. George E. Williams, Havelock, who has entered the military service.

NEW MEXICO

Personal.—Dr. Eugene M. Fisher, Roswell, who has been seriously ill with influenza is improved.——Dr. Perry M. Baker, Artesia, has established headquarters at the Carrizozo at the Dr. Lucas Hospital.——Dr. James M. Doughty has purchased the interests of his partner in the Tucumcari Hospital.

State Society Meeting Postponed.—The secretary of the New Mexico Medical Society announced that the annual meeting of the society has been indefinitely postponed after a careful investigation of the situation and after consultation with the Bernalillo County Medical Society which was to have been the host on that occasion. The large number of the members of the society in service and the few who could attend the meeting determined this action of the council.

NEW YORK

Staff of Bureau of Venereal Diseases.—Permanent appointments to the staff of the Bureau of Venereal Diseases of the New York State Department of Health have recently been made as follows: Drs. Joseph S. Lawrence, Albany, chief; Edward H. Marsh, Brooklyn, consultant; Walter S. Goodale, Buffalo, hospital and dispensary inspector and organizer; Frederick S. Honsinger, Syracuse, lecturer on social diseases, and Maud Casey, supervising nurse and social worker.

Influenza.—The total number of influenza cases in New York state from October 2, when the first signs of an epidemic became manifest, to November 1 was approximately 114,486. Since the epidemic started the state has had supervision over 126 nurses and thirty-eight physicians engaged in fighting the disease throughout the state. The services of ninety-four of the nurses and four of the physicians were obtained under the special appropriation of $50,000 made available by Governor Whitman for emergency medical and nursing service. One hundred and four communities in the state have been furnished nursing assistance. Of this number only fifty-five are today considered as under actual epidemic conditions. Thirty-four have been freed to the extent that they are now able to cope with the situation without further state aid.

New York City

License Revoked.—At its July meeting it is reported that the North Carolina State Board of Medical Examiners revoked the license of Dr. J. W. Summers, Charlotte, on the grounds of his having been sentenced to a term in prison for manslaughter in malpractice in performing an illegal operation.

Harvey Society Lecture.—The second lecture of the Harvey Society series will be delivered by Dr. Alonzo E. Taylor, Philadelphia, of the United States Food Administration of the War Trade Board, on "The World Food Situation," at the New York Academy of Medicine, November 20, at 8:30 p. m.

Hospital Notes.—An Emergency Hospital was established in Asheville for the care of influenza patients at the high school, October 19. There were 150 new cases of the disease, October 18. The staff of the institution is composed of Drs. Carl V. Reynolds, S. Westray Battle, Arthur W. Calloway, Lewis W. Elias, William C. Brownson, Charles H. Cocke, Arthur L. Denchfield, and Philip R. Terry.

More Buildings Taken for Government Hospitals.—In accordance with the plan of the Hospital Division of the Medical Corps of the U. S. Army which calls for the securing of at least 5,000 new beds each month, in addition to taking North Brother Island, the government has taken the nine buildings which are in Exposition Park, Rochester, N. Y., and the Westchester Almshouse, which after alterations will accommodate 2,000 patients. The alterations necessary to equip these newly acquired buildings for hospital purposes will cost approximately $175,000, and will be effected by Jan. 1, 1919.

After-Care of Influenza and Pneumonia Patients.—The health department began to make physical examinations to detect any ill after-effects among influenza patients at the different relief stations where physicians of the department are on duty, November 11. As an emergency measure food will be provided for the very needy. The health department in its effort to provide homes for children bereft of their parents during the epidemic, declares that from a cursory examination of death certificates 2,000 young children have been left orphans. The health department is particularly desirous of placing these children in good homes.

Polyclinic Hospital Offered to Columbia University.—At the meeting of the trustees of Columbia University, November 4, it was announced that the New York Polyclinic Hospital, by unanimous vote, had offered to transfer the property of that institution to Columbia University, with the provision that it be maintained and perpetuated for the public service and for advanced research in medicine and surgery. In response to this offer the trustees of Columbia University adopted resolutions, receiving with grateful appreciation the proposal by the trustees of the Polyclinic Hospital, and appointing a subcommittee to arrange the detailed terms and conditions of accepting the proposed gift. The university will not be able to use the hospital for some time to come as it is now in possession of the government and is conducted as a military hospital.

OHIO

Personal.—Dr. Herbert M. Platter, Columbus, has been elected secretary-treasurer of the Ohio State Medical Association, to fill the unexpired term of Dr. Clarence D. Selby, Toledo, resigned.——Dr. Charles Lukens, Toledo, has been elected councilor of the fourth district, to succeed Dr. Edwin A. Murbach, Archbold, who has resigned to enter the military service.——Dr. Henry W. Cook, Hicksville, is seriously ill at his home as the result of a cerebral hemorrhage.——Dr. Guy H. Williams, for fifteen years assistant superintendent of the Columbus State Hospital, has been appointed superintendent of the Cleveland General Hospital, to succeed Dr. G. A. Hyde, who has been made superintendent of the Massillon State Hospital, to succed Dr. Henry C. Eyman, who has resigned.

Care of Discharged Soldiers.—The construction of institutions for the care of discharged soldiers is a legitimate war measure and the need in Ohio is great. The state department of health has been notified of 865 discharges of Ohio soldiers on account of tuberculosis. Despite careful follow-up work, it has been found impossible to place more than thirty-one of these men in hospitals, where they would be given the care which they should have and which would protect their families and associates against possible infection. The department estimates that 400 of these men would be glad to enter sanatoriums, if facilities permitted this, and that many more men rejected by draft boards would also undergo treatment. To meet both this and the regular prewar demand Ohio has 1,570 hospital beds available to the public, and last year these beds were 90 per cent. occupied at all times, making it necessary for applicants to remain on waiting lists for long periods before gaining admission to hospitals. Enlargement and extension of existing hospitals in the state and establishment of new district sanatoriums are being urged by the department.

OREGON

Voluntary Commitment Law Asked.—Dr. R. E. Lee Steiner, superintendent of the State Hospital for the Insane, Salem, in his biennial report, recommends that on account of the number of nonresident insane persons brought into the state a voluntary commitment law should be enacted, which would enable patients to obtain treatment without having to go to court or to jail.

Personal.—Dr. George F. Koehler, Portland, has been appointed surgeon in chief of the National Guard of Oregon, with the rank of major, to succeed Dr. William M. Campbell, who has resigned to enter the United States Service.——Dr. Luther E. McDougal, Eugene, who has been ill with influenza, is reported to be convalescent.——Dr. Thomas W. Ross, Portland, has been commissioned acting assistant surgeon of the United States Public Health Service, with station at Camp Sherman, Chillicothe, Ohio.——Dr. Walter H. Lott, Westport, is reported to be seriously ill.——Dr. Margaret E. Pomeroy, Salem, is reported to be seriously ill in Portland with pneumonia following influenza.——Dr. Bertram R. Shoemaker has been appointed physician to the State Soldiers' Home, Roseburg, to succeed Dr. Earle B. Stewart, who has resigned to enter the military service.——Dr. Alvane C. Seely, Roseburg, has been appointed assistant surgeon of the United States Public Health Service and acting state health officer, with headquarters at Portland.——Dr. James H. Robnett, has been elected health officer of the public schools of Albany.——Dr. Harvey J. Clements has been appointed surgeon to the S. A. T. C. at Willamette University, Salem.

PENNSYLVANIA

Will Establish Science Hall.—The will of the late Dr. John C. McClenathan, Connellsville, shows the value of the estate to be approximately $160,000, of which the bulk is given to his widow, and at her death to be diverted to the trustees of Washington and Jefferson Colleges to erect a building to be known as the McClenathan Hall of Science.

Philadelphia

The Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $250, will be made on July 14, 1919, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be on any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the college on or before May 1, 1919. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned on application within three months after the award. No Alvarenga Prize for 1918 was awarded.

CANADA

Hospital News.—Old St. Andrews College, Toronto, which was taken over by the federal government for hospital purposes, is now receiving patients.

Appointments.—Major Charles McMane, North Vancouver, B. C., becomes A.D.M.S. at Quebec in place of Major George A. Winters, Toronto, who has jointed the Siberian Force; Capt. Adam F. Menzies has been appointed cholera expert for the Siberian Force; Capt. Percy H. Desnoes, New York City, becomes chief surgeon at the Fredericton Military Hospital, New Brunswick.

Influenza Decreasing.—Dr. Charles J. C. O. Hasting, M. O. H., Toronto, says the epidemic of influenza there is rapidly declining. On the middle of the past week the total number of deaths from all causes registered thirty-eight, while during the height of the epidemic they totalled as many as 150. Statistics are now being prepared of the deaths in all the hospitals in Toronto, so that the toll of influenza and the pneumonias may be computed.

Personal.—Dr. John R. Irwin, Cobourg, Ont., who has been overseas for the past three years with the C. A. M. C., has returned to Cobourg. He was decorated for devotion to duty in going to the help of some entombed men at great personal danger.——Dr. John M. Rogers, Ingersoll, Ont., who two years ago was nominated to contest South Oxford in the Liberal interest for the Ontario Legislature, has resigned.——Major W. Harley Smith, Toronto, is now with the Fourteenth General Hospital, B. E. F., France, being in charge of wards for officers, and having both surgical and medical cases. This hospital is established in a big hotel and in huts on the coast.

FOREIGN

Honorary Memberships for Americans in Leading French Medical Society.—The Société Médicale des Hôpitaux de Paris elected at a recent meeting, as corresponding members *honoris causa,* Dr. Alexander Lambert, the president-elect of the American Medical Association, director of the medical service of the American Red Cross in France; Col. James T. Case, editor of the *American Journal of Radiology* and chief of the radiologic service of the American Army in France; Prof. William S. Thayer of Johns Hopkins, consultant to the American Expeditionary Force; Prof. Morton Prince of Tufts College, New York; Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, and Prof. Beverley Robinson of the University and Bellevue Hospital in New York, a former intern of the Paris hospitals. At the same time, five British physicians were also elected, including Sir Almroth Wright, Sir Bertrand Dawson, Sir Thomas Barlow, Sir Dyce Duckworth and Sir William Leishman. The motion to elect these eleven honorary members was presented by Netter, the president of the society, Chauffard, Béclère and Major Rist. The latter had not long returned from a visit to America.

New International Ear, Nose and Throat Journal.—During the last two years there has been published at Stockholm the *Nordiskt Tidskrift för Otiatri, Rhinologi och Larynologi.* The editorial staff consists of Professors Schmiegelow of Copenhagen, Uchermann of Christiana, Af Forselles of Helsingfors, and Bárány of Upsala, with Prof. G. Holmgren of Stockholm as the editor in chief. The articles were in the various Scandinavian languages but were followed by a résumé in one of the "congress languages." The *Nederlandsch Tijdschrift* now announces that it has been decided to transform it into an international journal, to be called the *Acta Oto-Laryngologica,* to publish articles in the writer's own language, including French, German and English. A number of other specialists in the five neutral countries have been added to the editorial staff, including Professors Burger of Amsterdam, Kan of Leyden, Benjamins and De Kleijn of Utrecht, and Schutter of Groingen. It is hoped to obtain a world-wide circulation for this new international journal. It is to appear at irregular intervals as material accumulates, each part to consist of 500 or 600 pages, and the subscription per part is to be 20 Swedish crowns, about $5. Address Prof. H. Burger, Keizersgracht 317, Amsterdam. Our Nederlands exchange adds that this new undertaking is not only of scientific moment, but is a step on the road to an actual League of Nations. It urges physicians in the Nederlands, interested in these specialties and their borderlands, to seize the opportunity to present a favorable impression of their country's scientific achievements.

Winkler's Jubilee.—Professor Winkler of Utrecht completes twenty-five years of professional work this year, and Professor Pekelharing sketches in a recent issue of the *Nederlandsch Tijdschrift* Winkler's contributions to science, especially his work on the brain. To his initiative was due the foundation of the Central Institute for Research on the Brain, established in connection with the Institute for Anatomy at Amsterdam by the Brain Commission. It has been in operation several years, in charge of Dr. A. Kappers. Winkler is a leading member of the Brain Commission, organized by the International Association of Academies. The publication of an atlas showing the finest details of the microscopic anatomy of the brain and spinal cord was planned by the commission, but the work has been interrupted by the war. Only two of the members of the commission have done their part of the work; these are Winkler and Monakow of Zurich. Winkler's research on the brain has brought to his laboratory such men as Monakow, Golgi, Van Gehuchten, Edinger and Sherrington, among others, to discuss his views and study his microscopic specimens. Winkler's "Manual of Neurology," published simultaneously in Dutch and French, testifies to his indefatigable efforts to benefit the sick by delving into anatomy and physiology. Winkler is now 63. Until 1914 he was connected with the University of Amsterdam, but then accepted a call to Utrecht, attracted by the new model psychiatric clinic. He has never founded a "school," as conditions in the Netherlands do not foster the gathering of a school of student workers around a professor, but he has always been popular as a teaching professor.

BUENOS AIRES LETTER

BUENOS AIRES, October 7, 1918.

Pan-American University Interchanges

The faculties of the medical department of the universities of Buenos Aires and Montevideo have recently concluded an agreement by which they are to interchange professors monthly from May to October. The interchange professors are to lecture on the special subjects in the branch of medicine which their chairs represent. In conformity to this agreement, the Buenos Aires professors, Drs. G. A. Alfaro and A. Gutierrez have been lecturing in Montevideo. From Montevideo has come to Buenos Aires Prof. A. Turenne.

The professor of clinical neurology at Rio de Janeiro, Dr A. Austregesilo, has been spending some time in this city, visiting all its medical institutions in detail.

Several Argentine professors have been invited to the Eighth Brazilian Medical Congress which is soon to be held at Rio de Janeiro, and several have already left for Rio, including Drs. G. A. Alfaro, J. Spangenberg, J. Guglielmetti and others.

The professor of physiology at Rio de Janeiro, Dr. A. Osorio de Almeyda, has been visiting in Buenos Aires, and has been conferring with research workers here.

Reforms in University Administration

The acting interim dean, Dr. Canton, having served out the term, the *consejo directivo* of the university held a meeting and nominated Dr. A. Gandolfo to the position of dean. Dr. Canton wished to retain the dean-ship, but the *consejo* did not heed his appeal.

The national government has finally approved of the plan for reform of the statutes of the universities. The plan contains a number of changes sanctioned by the university centers, but some of the innovations are open to serious discussion.

The members of the *consejo directivo* for the various faculties in the university are to be nominated in a special assembly. This will designate also the delegates to the superior *consejo universitario* whose term of office is to be two years. The dean is to be elected in the same manner, and he is to hold office for three years, and can be reelected after being out of office for one term. The members of the *consejo* are to serve for three years.

The change which is the greatest innovation and the most open to discussion is the constitution of this assembly. It is to comprise the titular professors, with an equal number of associate professors (*suplentes*) and an equal number of the students of the last three years.

The right is granted for associate professors, graduates and other persons with proper credentials to give open courses of lectures which the faculty will consider valid. Attendance at classes is not compulsory.

The retirement of professors reaching the age limit—*la jubilacion*—is also to be enforced for those who have reached this age.

The appointment is also provided for of *interventores* in the different departments of the universities for the purpose of presiding at the new elections. Prof. J. Arce has been appointed *interventor* in the Facultad de Medicina.

Delegates to Conference on Hygiene, Microbiology and Pathology

The national government has appointed as its representatives in this conference which is to convene at Rio de Janeiro, October 15, Drs. A. Bachmann, Cases Irigoyen, E. Pagniez, A. Vidal and S. Mazza. It has been a matter for general surprise that the better elements have thus been excluded from these appointments, those which had been making preparations for this gathering, especially the members of the Instituto Bacteriologico of the Deparatmento Nacional de Higiene, especially as it is this institution that gave the initiative for these South American conferences. The members of this institution have prepared thirty-two articles and several addresses.

Habitual Constipation

The Sociedad Medica Argentina has been holding a series of meetings devoted to discussion of this subject from both the medical and surgical standpoints.

New Professor of Clinical Medicine

Dr. M. R. Castex has been appointed to the chair of clinical medicine to succeed the late Prof. A. Ayerza.

Prevention of Serum Sickness by Beef Serum

The experience of Drs. Fernandez and Zubizarreta at the Children's Hospital has brought them to different conclusions from those recently announced by Dr. Penna at the Academia de Medicina. They observed twenty instances of serum sickness among sixty-seven patients injected, and hence they are unable to confirm that beef serum is able to ward off serum by-effects.

MEXICO LETTER

MEXICO CITY, October 30, 1918.

The Leading National Medical Organization

The Academia Nacional de Medicina on October 1 entered on its fifty-fifth year of work. The dean of the University of Mexico, Sr. N. Macias, presided at the meeting. The officers that have been elected for the year 1918-1919 are: president, Dr. R. Cicero; vice president, Dr. E. F. Montaño; first secretary, Dr. D. Lopez, and second secretary, Dr. M. R. Soberon. The treasurer and editor of the *Gaceta Medica de Mexico*, the official organ of the Association, is Dr. E. Landa. [The *Gaceta* is now in the eleventh volume of the third series, and recently the issues have been condensed into two large numbers during the year. It is indexed and reviewed regularly in the Current Foreign Literature Department of THE JOURNAL.]

Influenza in Mexico

Influenza has spread with extraordinary rapidity throughout the City of Mexico. The disease has already caused numerous deaths. In some cases it takes the form of an extremely acute bronchopneumonia lasting two or three days. In other cases there is merely the simple catarrhal form, but with temperature up to 106 and 107. Copious epistaxis is a common accompaniment. Congress appropriated the sum of $200,000 for the Departamento de Salubridad to defray the first expenses connected with the campaign against this universal epidemic disease.

Campaign Against Venereal Diseases

The Sociedad Mexicana Sanitaria y Moral de Profilaxis de las Enfermedades Venereas has just organized and opened a free advisory clinic for applicants with gonorrhea or syphilis. Certain members of the society and other persons in the capital contributed funds for installing this *consultorio*. It is open daily, with physicians belonging to the society in charge.

PARIS LETTER

Paris, Oct. 17, 1918.

The Influenza Epidemic

The prevailing epidemic of grip continues to be the subject for discussion in medical gatherings. The Société médicale des hôpitaux de Paris devoted its last meeting to the discussion. It seemed to be the general opinion that the present epidemic, to date, is less severe than that of 1889, the number of cases in this epidemic totaling only about one third the number of cases occurring during the similar period in 1889. Taking it as a whole, the present epidemic from the bacteriologic and clinical point of view, is similar to the 1889 epidemic. There is, however, one great difference, and that is the age of those affected. In the 1889 epidemic older persons were affected mostly, while in the present epidemic nearly all the victims are young persons. This statement was made by Dr. Louis Rénon and it is supported by the observations of his colleagues. Dr. Souques, physician of the hospices de la Salpêtrière and de Bicêtre, stated that he had not seen a single case of grip among the inmates of these institutions, numbering more than 3,000 aged persons, while among the personnel of the hospitals, all young persons, dozens of cases occurred. It can be said that in the present epidemic only persons between 15 and 40 years of age are affected.

It was the unanimous opinion that malignant grip is grave by reason of the pulmonary and pleural complications. It is mainly the pneumococcus that is concerned in the pathogenesis of these lesions; the streptococcus is encountered less often. Serotherapy seems to be indicated in treatment. Drs. Rénon and Mignot have obtained excellent results from its use. Seven patients who developed pulmonary complications in the course of grip were treated by antipneumococcus serum; all recovered. Dr. Netter used the serum in twenty cases and obtained most satisfactory results. Drs. Josué, Florand and Sergent emphasized the importance of phenomena from suprarenal insufficiency in the course of grip, and advised the use of epinephrin in such cases.

The Conseil d'hygiène du département de la Seine likewise devoted its last session to the discussion of influenza. The permanent committee on epidemics was charged to draft suggestions which would prove useful to the people in aiding to avoid the disease.

Bacteriology of Influenza

At the last meeting of the Académie des Sciences, Dr. Roux, director of the Institut Pasteur, reported the results of experimental research on the pathogenesis of grip. This work was done on monkeys at first, then on the human, by Drs. Nicolle and Lebailly of the Institut Pasteur of Tunis. Their observations showed that the infection is carried during the active stage of the disease by the nasal and bronchial mucus of grip patients. The monkey can be inoculated with the virus applied to the nasal mucous membrane or injected under the conjunctiva. The symptoms of grip are manifested in about six days. A man developed the same symptoms in about the same time when inoculated subcutaneously with bronchial mucus diluted ten times with physiologic saline solution. The infecting agent seems to be a very small micro-organism which passes through the Chamberland filter and which is distinct from all other microbes hitherto described, and notably from the bacillus of Pfeiffer. The subcutaneous injection of this organism into humans reproduces the disease. Intravenous injection, however, does not convey the disease to man or monkey.

Unrecognized Septicemias

Drs. Gauléjac and Nathan called attention at one of the recent meetings of the Académie de médecine to a class of latent apyretic septicemias, monosymptomatic, of which the most perfect type is that following the crushing of spongy bone. As a rule these cases are apyretic, not painful, and no matter how severe or extensive the contusion of the bone may be, they go unrecognized unless a most careful and thorough search is made. Pain, discomfort and loss of function appear about the tenth day, when the lesion of the spongy diaphyseal bone extends to the compact bone and to the joint. During this stage of the affection only one sign or symptom makes its appearance—a relative tachycardia. With an even temperature of 37.5 C., the pulse rate is 90, 100, 110. No other sign or symptom is present. It is always a case of septicemia, because in almost every instance blood culture reveals the enterococcus, more rarely the pneumobacillus of Friedlaender and they most certainly come from the bone focus because cultures made from excised bone nearly always yield one or the other of these organisms. The septicemia arises only in the bone, and when the contused bone is completely excised, the local lesion is repaired rapidly, and further septicemia does not occur, or is insignificant in degree. If the excision is incomplete, chronic osteo-arthritis develops, with a tendency to ankylosis, and a prolonged state of septicemia. The patient becomes pale, loses appetite and weight, becomes cachectic, and sometimes, months after the traumatism, a positive blood culture is obtained. These sequelae occur often.

This latent and monosymptomatic septicemia is essentially characteristic of lesions limited to the spongy bone, but when the soft parts are involved, there occur as a rule a febrile reaction and pain which overshadow the symptom from the bone lesion. All sorts of febrile septicemias with enormous oscillations may be observed, and even in the purely bone cases one may find associated with the enterococcus and the pneumobacillus the proteus, mesentericus, tetragenus, pyocyaneus, staphylococcus, and even gas bacilli.

The diagnostic value of the symptomatology of this form of septicemia is thus emphasized, and the pulse and blood culture permit control of any surgical intervention that may be undertaken and its being made thorough in time.

MADRID LETTER

Madrid, Oct. 1, 1918.

Persecution of Loyal Physician

Dr. Gomez Casas, physician of the Almeira prison, reported to his superiors the presence of influenza among the inmates of the prison early in the first epidemic. The governor of Almeira was not pleased at having his province invaded by the disease, and he summoned Dr. Casas and ordered him to sign a written report to the effect that he had been mistaken in his diagnosis, and retract his statements as to the existence of influenza in the prison. Dr. Casas refused to do this and he was fined. The amount of the fine was not much, but it was important because it signified arbitrary officialdom and lack of appreciation of the conscience and moral courage of a man devoted to science. The medical corps in the province of Almeira on this occasion set an example of loyalty. The Colegio Medico publicly announced that it would stand by Dr. Casas and subscribe the amount to pay the fine which a governor ignorant of his duties had imposed on him. At the same time an official protest was filed with the central public health authorities, the Consejo de Sanidad.

Payment of Health Officers by the State

The case of Dr. Casas is a sample of the restrictions imposed by the local authorities on the activity of physicians, but unfortunately for the latter their sufferings in very many cases and their complaints have motives more prosaic and at the same time more vitally important for their own existence. The immense majority of the population of Spain scattered through rural districts and hamlets get their only medical care from the so-called *medicos titulares*, physicians paid by the local authorities. As many of these hamlets are small and poor, the sums which they can afford to pay for the medical care of their poor neighbors (and nearly all are poor in these localities) is inadequate to support a physician. One single physician may have to visit two, three, four, up to eight or ten of these villages, many miles apart, and by ways accessible only on horseback as there are no practicable roads, in mountain zones where fogs and snow are almost constant. Sometimes on account of the actual poverty of the villages and hamlets, and at other times on account of political organizations to which the physician does not belong or is opposed, the local authorities exhaust the money at their command without paying the physician's salary, and years may pass without his receiving his money, as he is put off with promises which are fulfilled tardily, inadequately or never, as the case may be.

Similar conditions used to prevail in respect to schoolteachers, until one minister of public instruction, intelligent and impressed by the realities of the life of the nation, the Count de Romanones, ordered that the teachers in public schools should be paid by the government. Since then other ministers of public instruction have carried out further reforms in this line so that today the schoolteachers have a brilliant present and a splendid future before them. A group of physicians who have attained enviable renown and positions as statesmen have organized a movement for the payment of the *medicos titulares* by the government in the same way as the schoolteachers. This leading group of physicians in the senate is headed by Dr. Cortezo, a former minister of public instruction and member of the cabinet, the Consejo de Estado, Dr. Pulido, vice president of the senate, Dr. Gimeno, formerly minister of the navy and Dr. F. Rodriguez, also at one time minister of public instruction. Paid by the state, the *medicos titulares* would then be independent of petty local politics, and they could act with greater force and directness in matters affecting the public health, in which now they have little if any influence, directly to the detriment of all interested, local politicians being usually ignorant of the principles of sanitary science.

The great difficulty which the *medicos titulares* encounter in their aspirations is the general agitation for rebellion against too much centralization of power. Politics recently, after a period of centripetal tendency, during which all attributes and all authority were diverted to the central head, has lately become centrifugal, seeking to spread authority around among the provinces and the municipalities. As far as public health matters have been concerned and the support of those entrusted with carrying out provisions for the public health, only the centrifugal principle has prevailed, and this has demonstrated its inefficacy. In spite of the modern tendencies for decentralization and distribution of authority, in matters of public health there can be no question that a unified and graduated system with payment of the officials by the state is the only efficient principle.

LONDON LETTER

London, Oct. 15, 1918.

German Savagery to Prisoners

The report of Mr. Justice Younger's committee on the treatment by the Germans of prisoners of war taken during the spring offensives of 1918 has been issued. As in all previous reports, the tale is one of monotonous barbarity enlightened at only rare intervals by the conduct of a German officer who can be described as human. The statements were collected of upward of seventy British prisoners who succeeded in escaping. Each man took his life in his hand; but as one of them, Corporal A. J. Coney, said, "All the men in our compound felt that they might as well risk being killed getting back to British lines as remain in German lines to be killed by our shells or starved by Germans." The treatment of the prisoners is indicated by the statement of a German officer, March 22, at Marchiennes: "We will break your brave English hearts tomorrow." After capture the men were in nearly every instance left without food for periods varying from twenty-four to forty-eight hours, during which they were kept constantly on the march. Wounded prisoners got no dressing or attention and were forced to march with the others. Even the French peasants who tried to give the prisoners food were prevented, and when they reached water the men were not allowed to fall out to drink it. There was an utter disregard by the German command for its obligations whether entered into before or during the war. Prisoners were employed under pain of death on operations directly concerned with the German offensive. They were billeted in buildings, such as churches, without a roof, and with nothing to lie on or only verminous straw. The following is a typical day: Reveille at 3 a. m., a drink of coffee but no food. Marched to work, which would start about 8 a. m. Rest from 12 to 1; then work to 5 p. m. Nothing to eat until 7 p. m., when soup made of a kind of fried fish and lentils and a loaf to three men were given. The prisoners, of course, became very weak and exhausted. During the spell between 12 and 1 they collected nettles, which they brought to the camp at night to eat. The result was that most of them became ill with bad feet and dysentery, but they were still made to work. The camp was in a very insanitary condition, and there were no beds or blankets or straw. The prisoners of the Army Medical Corps volunteered to take over the sanitary arrangements of the camp, but this was refused. Of the hospital at Valenciennes an escaped prisoner gives a gruesome account. The food was bad, the sanitary arrangements appalling. Eggs were sometimes issued to the men who had lost limbs, but the German orderlies stole them and in some cases even the clothing of the prisoners, who had to lie in bed with nothing on except the bed covering made of papier mâché. One man, Private Ellis, lay in bed with a bullet wound in his lung for some days unattended. As he was in great pain he was crying, and was taken to a German doctor, who hit him a punch on the jaw. He came back crying and died next morning.

Boycott of German Scientists

The interallied conference on the future of international organization in science has met in London and unanimously adopted a statement which is intended to serve as a preamble to a number of resolutions, dealing with the withdrawal of the Allied nations from existing international associations and the formation of new ones to take their place. The confirmation of the academies represented at the conference is required before the text of the resolutions can be made public: "When more than four years ago the outbreak of war divided Europe into hostile camps, men of science were still able to hope that the conclusion of peace would join at once the broken threads, and that the present enemies might then once more be able to meet in friendly conference, uniting their efforts to advance the interests of science, for ever since the revival of learning in the middle ages, the prosecution of knowledge has formed a bond strong enough to resist the strain of national antagonism. And this bond was strengthened during the latter part of last century, when branches of science developed requiring for their study the cooperation of all the civilized nations of the world. International associations and conferences rapidly multiplied, and the friendly intercourse between the learned representatives of different countries grew more intimate, in spite of their political differences. In former times, war frequently interrupted the cooperation of individuals without destroying the mutual esteem based on the recognition of intellectual achievements; peace then soon effaced the scars of a strife that was ended. If today the representatives of the scientific academies of the Allied nations are forced to declare that they will not be able to resume personal relations in scientific matters with their enemies until the Central Powers can be readmitted into the concert of civilized nations, they do so with a full sense of responsibility; and they feel bound to record the reasons which have led them to this decision. Civilization has imposed restrictions on the conduct of nations which are intended to serve the interests of humanity and to maintain a high standard of honor. Such are the recognition of the sanctity of treaties — especially those designed to apply to a state of war—and the avoidance of unnecessary cruelties inflicted on civilians. In both these respects the Central Powers have broken the ordinances of civilization, disregarding all conventions and unbridling the worst passions which the ferocity of war engenders. War is necessarily full of cruelties; individual acts of barbarity cannot be avoided and have to be borne. It is not of these we speak, but of the organized horrors encouraged and initiated from above with the sole object of terrorizing unoffending communities. The wanton destruction of property, the murders and outrages on land and sea, the sinking of hospital ships, the insults and tortures inflicted on prisoners of war, have left a stain on the history of the guilty nations which cannot be removed by mere compensation of the material damage inflicted. In order to restore the confidence, without which no scientific intercourse can be fruitful, the Central Powers must renounce the political methods which have led to the atrocities that have shocked the civilized world."

The Influenza Epidemic

The influenza epidemic, which apparently had passed off, has undergone recrudescence in as widespread a form as before. The public health committee of the London County Council reports that the influenza epidemic between June 15 and August 3 caused from 1,600 to 1,700 deaths in London. The clinical features leave no doubt that the disease was identical with the epidemic influenza of 1890, but the difference in age incidence is noteworthy. In 1918, as compared with earlier epidemics, the incidence is higher between ages 5 and 45, and lower at ages over 45. Concurrently with influenza mortality, there was a large increase in deaths from bronchitis and pneumonia; and as this increase cannot be accounted for by any abnormal climatic conditions by which these diseases are governed, it is reasonable to assume that the major part of the added deaths from these causes are of influenzal origin. The epidemic was first reported in Spain. Generally speaking, it moved northward in Europe and eastward in India, and this movement would be consistent with a hypothesis of spread from the Mediterranean. In previous similar epidemics the progression has been westward in Europe, the country of origin usually being Russia. The war, however, has fundamentally changed the general character of European traffic—that from east to west being suspended, while the north and south traffic has been greatly augmented. The abnormal progression of the present epidemic may have been mainly determined by the changed lines of intercommunication.

Deaths

James Edward Moore ⊕ Minneapolis; one of the most notable surgeons of the Northwest; died at his home in Minneapolis, November 2, from pernicious anemia. He was born in Clarksville, Pa., March 2, 1852, pursued his medical studies at Bellevue Hospital Medical College, New York City, from which he was graduated in 1873. After three years of practice in Fort Wayne, Ind., six years in Emlenton, Pa., and three years of postgraduate study abroad, he located in Minneapolis in 1882. He specialized in surgery since 1888. He had been surgeon in chief of the Northwestern Hospital, Minneapolis, since 1907; and connected with the University of Minnesota since its organization in 1888; had been professor of surgery in its medical department since 1904, and chief of that department since 1908. He was made chairman of the Section on Surgery, General and Abdominal, of the American Medical Association in 1902, and had been a member of the Judicial Council of the Association since 1911. He was president of the Western Surgical Association in 1902, and was an honorary member of the American Orthopedic Association. He was an extensive contributor to the literature of his specialty, and was the author of Moore's Orthopedic Surgery, which was published in 1898.

James Edward Moore, M.D., 1852-1918

James Jackson Putnam ⊕ Boston; Harvard Medical School, 1870; aged 72; distinguished as a neurologist; lecturer on diseases of the nervous system in his alma mater from 1872 to 1875; clinical instructor from 1875 to 1885; instructor from 1885 to 1893; professor from 1893 to 1912, and professor emeritus from 1912; neurologist to the Massachusetts General Hospital from 1874 to 1909, and since that time consulting physician to the same institution; consulting neurologist to many public and private hospitals; author of several works, principal among which was the Memoirs of Dr. James Jackson; died at his home, November 4, from heart disease.

Lieut. John Gabriel Long, M. C., U. S. Army ⊕ Lancaster, Pa.; Johns Hopkins University, Baltimore, 1916; aged 27; resident surgeon at St. Agnes' Hospital, Baltimore, until June, 1918, when he became assistant instructor in treatment of infected wounds at the War Demonstration Hospital of the Rockefeller Institute for Medical Research, New York City; died in St. Joseph's Hospital, Lancaster, October 24, from pneumonia following influenza.

Jesse Sidney Wyler ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1904; aged 39; a member of the Cincinnati Academy of Medicine and American Academy of Ophthalmology and Oto-Laryngology; assistant clinical professor of ophthalmology in the University of Cincinnati; attending ophthalmologist to the Jewish Cincinnati General Hospital; died at his home in Avondale, Cincinnati, October 23, from bronchial pneumonia following influenza.

James Gifford Lynds ⊕ Ann Arbor, Mich.; University of Michigan, Ann Arbor, 1888; aged 55; acting professor of gynecology and obstetrics in his alma mater from 1897 to 1898; and clinical professor of obstetrics and demonstrator of gynecology and obstetrics until 1901; director and chief surgeon of the Ann Arbor Sanitarium; died at his home, October 24, from pneumonia following influenza.

William W. Hipolite, DeVall Bluff, Ark.; University of Michigan, Ann Arbor, 1857; aged 84; and once president of the Prairie County Medical Society; a member of the Arkansas Medical Society; formerly surgeon of the Memphis and Little Rock Railroad; surgeon in the Confederate Service during the Civil War; died at his home, October 24.

Isaac Norris, Philadelphia; University of Pennsylvania, Philadelphia, 1855; aged 85; from 1856 to 1876 professor of chemistry in the Central High School; director of Franklin Institute; a member of the American Philosophical Society and of the Academy of Natural Sciences; one of the secretaries of the College of Physicians of Philadelphia; died in Florence, Italy, October 22.

Joseph Kaufman ⊕ New York City; Long Island College Hospital, Brooklyn, 1910; aged 30; a member of the American Urological Association; genito-urinary surgeon to the People's Hospital, and chief of the urological clinic of St. Mark's Hospital; secretary of the New York Physicians' Association; died at his home, October 28.

Joseph T. Cox, Penn Yan, N. Y.; Chicago Homeopathic Medical College, 1888; aged 52; at one time a member of the Medical Society of the State of New York; for several terms coroner of Yates County; and up to the time of his last illness health officer of Penn Yan; died at his home, October 25, from pneumonia following influenza.

William Francis Conway, Albany, N. Y.; Albany (N. Y.) Medical College, 1909; aged 31; a member of the Medical Society of the State of New York; attending ophthalmologist and otologist to the Infants Home, and surgeon to the Eye, Ear, Nose and Throat Clinic, Albany; died at his home, November 1, from influenza.

John Peter Heyen, Northport, N. Y.; New York University, New York City, 1883; aged 59; a member of the Medical Society of the State of New York; health officer of Northport, and Suffolk County, since 1900; surgeon to the Huntington Hospital; formerly a druggist; died at his home, October 30.

Marcel Joseph De Mahy, New Orleans; Tulane University, New Orleans, 1910; aged 32; a member of the Louisiana State Medical Association, and a specialist in neurology; a member of the staff of the Touro Infirmary; died in that institution, October 15, from pneumonia following influenza.

Lieut. Cole Fro Smith, M. C., U. S. Army ⊕ San Antonio, Texas; University of Texas, Galveston, 1910; aged 34; a specialist in diseases of the skin; on duty at the Embarkation Hospital, Camp Stewart, Newport News, Va.; died in that institution, October 16, from pneumonia following influenza.

Charles Sudranski ⊕ Greencastle, Ind.; Medical College of Indiana, Indianapolis, 1905; aged 38; died, October 27, from an incised wound of the throat, self-inflicted, it is believed, with suicidal intent, while despondent on account of the death of his wife from influenza.

Lieut. Alexander Renold Lundgren, M. C., U. S. Army ⊕ Spokane, Wash.; John A. Creighton Medical College, Omaha, 1907; aged 34; surgeon for the Spokane International Railway, and awaiting his call to service; died at his home, October 24, from pneumonia following influenza.

Walter L. O'Hagan, Pittsburgh; University of Pittsburgh, 1907; aged 36; at one time a member of the Medical Society of the State of Pennsylvania; for some time a school physician of Pittsburgh; died in Mercy Hospital, Pittsburgh, October 31, from pneumonia following influenza.

John Charles Brown, Battle Creek, Mich.; Fort Wayne (Ind.) College of Medicine, 1886; aged 65; a member of the Michigan State Medical Society; once president of the Calhoun County Medical Society; died at his home, about October 28, from pneumonia following influenza.

Erastus E. Case, Hartford and Windsor Heights, Conn.; New York Homeopathic Medical College, New York City, 1874; aged 71; president of the Connecticut Homeopathic Medical Society in 1888; died at his home in Windsor Heights, October 27, from pneumonia.

Britton Emery Taylor, Brighton, Mo.; National University of Arts and Sciences, St. Louis, 1912; aged 30; a member of the Missouri State Medical Association; died in the Springfield Hospital, Springfield, Mo., October 22, from bronchial pneumonia following influenza.

Chesley Lightbourne Evans, Los Angeles, University of California, San Francisco, 1912; aged 30; a member of the Medical Society of the State of California; house physician of the Good Samaritan Hospital, Los Angeles; died in that institution, October 25, from pneumonia.

Thomas Justin Aller ⊕ Philadelphia, University of Pennsylvania, Philadelphia, 1910; aged 33; also a dentist; who had served with a medical unit in France, but returned to America in the spring of 1918; died at his home, October 29, from pneumonia.

Lieut. Gordon Greenleaf Williford, M. C., U. S. Army ⊕ Tifton, Ga.; Emory University, Atlanta, 1914; aged 33; on duty at Camp Joseph E. Johnston, Jacksonville, Fla.; died in the base hospital at that post, October 13, from pneumonia following influenza.

Walter F. Payne, Prairie Creek, Ind.; State College of Physicians and Surgeons, Indianapolis, 1907; aged 37; a member of the Indiana State Medical Association; died at his home, October 24, from pneumonia and meningitis, following influenza.

Roy Richard Longino, Fort Stockton, Texas; Tulane University, New Orleans, 1911; aged 30; a member of the State Medical Association of Texas; and a specialist on diseases of the eye, ear, nose and throat; died at his home, recently, from influenza.

John F. Dunwoody, Detroit; Detroit College of Medicine and Surgery, 1911; aged 34; a member of the Michigan State Medical Society; for two years a member of the staff of St. Mary's Hospital, Detroit; died at his home, October 20, from pneumonia.

Nicholas Shelby Veatch ⊕ California, Pa.; University of Pennsylvania, Philadelphia, 1873; aged 75; while going over a grade crossing at Phillipsburg, Pa., October 25, was struck by a train, receiving injuries from which he died, a short time later.

Asst. Surg. Lawrence Lyle McLendon, Lieut. (j. g.), U. S. N. R. F. ⊕ Opelika, Ala.; Emory University, Ga.; aged 25; intern in the Wesley Memorial Hospital, Atlanta; died in that institution, October 21, from pneumonia following influenza.

Lieut. Joseph Harold Boyes, M. C., U. S. Army ⊕ Hebron, Neb.; Ensworth Medical College, St. Joseph, Mo., 1893; aged 49; founder and owner of the Blue Valley Hospital, Hebron; died at his home, October 24, from pneumonia following influenza.

Charles Byron Tefft, Utica, N. Y.; Albany (N. Y.) Medical College, 1864; aged 80; a member of the Medical Society of the State of New York; twice coroner of Oneida County; died in a hospital in Utica, October 31, from cerebral hemorrhage.

Lieut. Robert Harrison Murdock, M. C., U. S. Army ⊕ Wilkes-Barre, Pa.; Hahnemann Medical College, Philadelphia, 1913; aged 28; assigned to duty with the Forty-Seventh Infantry overseas, was recently killed in action in France.

Walter Eugene Gregory ⊕ Dansville, N. Y.; University of Buffalo, N. Y., 1889; aged 61; a specialist in nervous diseases and a member of the staff of the Jackson Health Resort, Dansville; died at his home, October 26, from pneumonia.

Wallace Winn Bacon, Albany, Ga.; New York University, New York City, 1870; aged 69; a member of the Medical Association of Georgia; city physician of Albany, and physician of Dougherty County; died at his home, October 24.

Arthur Hardy Cutter ⊕ Lawrence and Methuen, Mass.; Harvard Medical School, 1901; aged 45; for several years chief of the surgical staff of the Lawrence General Hospital; died at his home in Methuen, October 4, from pneumonia.

William Cletus Cooney, Indiana Harbor, Ind.; Chicago College of Medicine and Surgery, 1917; aged 23; physician for the Inland Steel Company of Indiana Harbor; died in Mercy Hospital, Gary, Ind., October 11, from pneumonia.

Ralph Waldo Homan, Webster City, Iowa; State University of Iowa, College of Homeopathic Medicine, Iowa City, 1894; aged 49; formerly a member of the faculty of his alma mater; died at his home, October 31, from cerebral embolism.

Miles Underwood Lieser, Vancouver, Wash.; University of Oregon, Portland, 1908; aged 39; at one time a member of the Washington State Medical Association; died at his home, October 25, from pneumonia following influenza.

Rufus Alvin Egbert, Custer City, Pa.; University of Michigan, Ann Arbor, 1875; aged 69; a member of the Medical Society of the State of Pennsylvania; died at his home, November 5, from pneumonia following influenza.

William James Churchill, Longmont, Colo.; Medico-Chirurgical College of Philadelphia, 1905; aged 42; a member of the Colorado State Medical Society; died in the Longmont Hospital, October 25, from influenza.

William James Backus, Stockton, Calif.; Trinity Medical College, Toronto, Ont., 1904; aged 28; a member of the Medical Society of the State of California; died at his home, October 27, from pneumonia following influenza.

William Glenn Miller, Morrisville, Mo.; Barnes Medical College, St. Louis, 1909; aged 35; a member of the Missouri State Medical Association; died at his home, September 29, from bronchial pneumonia following influenza.

Thomas Garfield Dodds, Oakland, Calif.; University of California, San Francisco, 1907; aged 40; at one time a member of the Medical Society of the State of California; died at his home, October 27, from influenza.

Lieut. Claude Dean, M. C., U. S. Army ⊕ Bogalusa, La.; on duty at Fort Oglethorpe, Ga.; Tulane University, New Orleans, 1914; aged 33; died at Fort Oglethorpe, October 20, from pneumonia following influenza.

Hervey S. Keller, Frankfort, Ky.; Pulte Medical College, Cincinnati, 1892; aged 47; for five months connected with the Santa Fe Coast Line Hospital, Albuquerque, N. M.; died at his home in that city, October 28.

Michael John Shiel, Indianapolis; Indiana University, Indianapolis, 1914; aged 32; a member of the Indiana State Medical Association; died in St. Francis' Hospital, Indianapolis, October 20, from pneumonia.

Robert Grosvenor, Newport, R. I.; College of Physicians and Surgeons in the City of New York, 1918; aged 26; died in the Waldorf-Astoria Hotel, New York City, October 28, from pneumonia following influenza.

Myron E. Stephens ⊕ Gardiner, N. Y.; Albany (N. Y.) Medical College, 1888; aged 63; health officer of Gardiner, and county physician of Ulster County; died at his home, about October 29, from influenza.

Lieut. James Gordon DeVane, M. C., U. S. Army ⊕ Adel, Ga.; Atlanta (Ga.) School of Medicine, 1911; aged 32; a member of the Medical Association of Georgia; died at his home, October 21, from influenza.

Andrew Joseph Mackay, Salem, Mass.; College of Physicians and Surgeons, Baltimore, 1902; aged 39; at one time an official of the health department of Salem; died at his home, October 29, from acute gastritis.

James Gladney Evans, Farmerville, La.; Vanderbilt University, Nashville, Tenn., 1898; for eight years coroner of Union parish; died at his home, about October 23, from pneumonia following influenza.

Clark L. Myerly, Burr Oak, Kan.; University Medical College, Kansas City, Mo., 1913; aged 32; a member of the Kansas Medical Society; died at his home, October 21, from pneumonia following influenza.

Harry Andrews Mills, Jacksonville, Fla.; Medical College of Ohio, Cincinnati, 1904; aged 38; a member of the Florida Medical Association; died at his home, October 16, from pneumonia following influenza.

Perry Ped Laughlin, Steubenville, Ohio; Toledo (Ohio) Medical College, 1913; aged 34; a member of the Ohio State Medical Association; died at his home, October 24, from pneumonia following influenza.

Joseph H. Blatner, Albany, N. Y.; Albany (N. Y.) Medical College, 1872; a member of the Medical Society of the State of New York; died, October 27, from injuries received when run down by an automobile.

Charles Robert Blake, Dillon, Mont.; Rush Medical College, 1913; aged 33; a member of the Medical Association of Montana; died at his home, about October 30, from pneumonia following influenza.

Herbert Eddes Brown, Houston, Texas; Memphis (Tenn.) Hospital, Medical College, 1901; aged 43; at one time a member of the State Medical Association of Texas; died at his home, October 25.

Lieut. Dorsey Elbrooks Payne, M. C., U. S. Army ⊕ Cordele, Ga.; Meharry Medical College, Nashville, Tenn., 1917; aged 25; died at his home, October 8, from pneumonia following influenza.

Thomas Joseph Conners, West Haven, Conn.; University of Maryland, Baltimore, 1912; aged 28; died at the home of his parents at Shelton, Conn., October 24, from pneumonia following influenza.

Rufus K. Merriam, Fort Rock, Ore.; Starling Medical College, Columbus, Ohio, 1892; aged 49; died in St. Elizabeth's Hospital, Baker City, Ore., October 29, from pneumonia following influenza.

Lieut. Lewis Zion, M. C., U. S. Army ⊕ New York City; College of Physicians and Surgeons in the City of New York, 1915; aged 29; died at Fort Slocum, N. Y., October 31, from pneumonia.

Edward Bulger Chapman, Brockport, N. Y.; University of Michigan, Homeopathic Medical School, Ann Arbor, 1907; aged 36; died at his home, October 26, from pneumonia following influenza.

Lieut. Wayne Person Hanson, M. C., U. S. Army ⊕ Los Angeles; Jefferson Medical College, 1912; aged 30; died in Philadelphia, October 26, from bronchial pneumonia following influenza.

Lieut. Milton Sylvester Sell, M. R. C., U. S. Army ⊕ Pittsburgh; University of Pittsburgh, 1908; aged 40; died at the home of his brother in North Side, Pittsburgh, November 5.

William Waller Vest, Clarksville, Va.; Medical College of Virginia, Richmond, 1901; aged 44; a member of the Medical Society of Virginia; died at his home, October 25, from pneumonia.

Harleston Read Simons ⊕ Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1909; aged 32; died at his home, October 21, from pneumonia following influenza.

Samuel Donald Stout, Cleveland; University of Texas, Galveston, 1918; aged 23; an intern in the City Hospital, Cleveland; died in that institution, October 1, from pneumonia.

William Henry Monagan, Mount Alton, Pa.; University of Pittsburgh, 1912; aged 37; a member of the Medical Society of the State of Pennsylvania; died at his home, recently, from influenza.

John S. Wood, Hot Springs, Ark.; Tulane University, New Orleans, 1906; aged 35; health officer of Garland County; died at his home, October 27, from pneumonia following influenza.

Lewis F. Frey, Baltimore; Baltimore Medical College, 1888; aged 52; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, November 1, from heart disease.

Solon Slade Barnette, Kilgore, Texas; Universities of Nashville and Tennessee, Nashville, 1910; aged 34; died at his home, October 21, from pneumonia following influenza.

George O. Quesenberry ⊕ Hinton, W. Va.; College of Physicians and Surgeons, Baltimore, 1887; aged 55; died at his home, October 20, from pneumonia following influenza.

Julian Ormal Walter ⊕ Bristol, Ind.; Indiana University, Bloomington and Indianapolis, 1912; aged 35; died at his home, October 28, from pneumonia following influenza.

Frank Townsend Stannard ⊕ Troy, N. Y.; Albany (N. Y.) Medical College, 1888; aged 52; a specialist in compensation insurance; died at his home, October 29, from influenza.

Hiram Pacco Whitford, Bridgewater, N. Y.; Eclectic Medical Institute, Cincinnati, 1860; aged 92; for many years a justice of the peace; died at his home, October 28.

William Elmer Kiser ⊕ Bellaire, Ohio; Cleveland-Pulte Medical College, Cleveland, 1911; aged 33; died at his home, October 25, from pneumonia following influenza.

Frederick Bellosa, New Haven, Conn.; Yale University, New Haven, 1872; aged 75; a member of the Connecticut State Medical Society; died at his home, October 20.

Donald Cuyler McKinnon, Lowell, Mass.; Tuft's College, Boston, 1918; aged 23; intern in the Lowell Corporation Hospital; died, September 28, from influenza.

George W. Betson, Jr., Quantico, Md.; Baltimore Medical College, 1905; aged 43; died at his home, about October 27, from pneumonia following influenza.

J. Edwin E. Olander ⊕ St. Paul; University of Minnesota, Minneapolis, 1904; aged 41; died at his home, October 25, from pneumonia following influenza.

Richard H. L. Garrett, Sellers, Ala.; Maryland Medical College, Baltimore, 1902; aged 38; died at his home, October 25, from pneumonia following influenza.

William Wilson Cassidy ⊕ Durand, Wis.; University of Illinois, Chicago, 1900; aged 42; died at his home, October 25, from pneumonia following influenza.

Abbott Lathrop Cooley ⊕ Chicopee Falls, Mass.; University of Michigan, Ann Arbor, 1897; aged 60; died at his home, October 28, from pneumonia.

John Smits ⊕ Leadville and Glenwood, Colo.; University of Paris, France, 1904; aged 49; died at his home in Glenwood, October 26, from pneumonia.

Lee Franklin McKay, Martin, Tenn.; Vanderbilt University, Nashville, Tenn., 1897; aged 44; dropped dead in Illinois Central Park, Martin, October 25.

Loyal Maximilian Martin ⊕ Newkirk, Okla.; Rush Medical College, 1913; aged 31; died at his home, October 19, from pneumonia following influenza.

Theodore John Trautmann ⊕ Hayti, Mo.; Marion-Sims Medical College, St. Louis, 1899; aged 43; died at his home, October 16, from pneumonia.

William J. Cook, Long Beach, Calif.; Baltimore Medical College, 1895; aged 48; died at his home, October 26, from pneumonia following influenza.

Ottmar von Schallern ⊕ Ripon, Wis.; University of Illinois, Chicago, 1891; aged 70; for thirty years a druggist of Ripon; died at his home, October 21.

George Washington Burk, Sisson, Calif.; Cooper Medical College, San Francisco, 1893; aged 46; died at Yreka, Calif., October 24, from pneumonia.

John Garnes Craig, Chicago; University of Michigan, Ann Arbor, 1891; aged 53; died at his home, November 6, from carcinoma of the tongue.

Richard A. Hasbrouck, Salt Lake City, Utah; Bennett Medical College, Chicago, 1882; aged 60; died at his home, October 24.

Albert Guy Alley ⊕ Minneapolis, Minn.; University of Minnesota, Minneapolis, 1905; aged 38; died in St. Paul, October 25.

Clinton Charles Moffat ⊕ Prosser, Wash.; University of Oregon, Portland, 1914; aged 35; died at his home, about October 29.

John Edward Wilson, Denver; Harvard Medical School, 1905; aged 39; died at his home, October 24, from influenza.

Arthur James Todd, New Boston, N. H.; Boston University, 1884; aged 52; died at his home, about October 15.

William Joffee ⊕ Chicago; Rush Medical College, 1904; aged 38; died at his home, October 21, from pneumonia.

Albert Roy Richey, Herreid, S. D.; State University of Iowa, Iowa City, 1905; died at his home, October 16.

William Mann Radcliff, Los Angeles; Jefferson Medical College, 1889; died at his home, October 22.

Marriages

Capt. Solon Mitchell Langworthy, M. C., U. S. Army, Cedar Rapids, Iowa, on duty with the American Expeditionary Forces in France, to Miss Madeleine Thomas of New York, in Paris, October 1.

Lieut. John Philip Strickler, M. C., U. S. Army, San Francisco, on duty at Camp McDowell, Angel Island, Calif., to Dr. Florence Edetha Dunlop, also of San Francisco, October 24.

Lieut. Francis X. McGovern, M. C., U. S. Army, on duty at Walter Reed General Hospital, Washington, D. C., to Miss Lottie Brown of Washington, D. C., October 30.

Asst. Surg. Frank Mullen Cannon, Lieutenant (Junior Grade), U. S. Navy, Great Lakes, Ill., to Miss Katherine McGovern of Vaile, La., at Great Lakes, October 30.

Lieut. Lester Charles Scully, M. C., U. S. Army, San José, Calif., on duty at Camp Logan, Texas, to Miss Gladys Neilson of Berkeley, Calif., at Camp Logan, recently.

Lieut. Leonard J. Murphy, M. C., U. S. Army, Fairland, Ill., on duty at Camp Grant, Rockford, Ill., to Miss Rosalie Dulaney of Slater, Mo., October 23.

Major Everett Logan Goar, M. C., U. S. Army, to Miss Italia West, both of Houston, Texas, October 27.

Hans Christian Holm, Washington, D. C., to Miss Alice May Butler of Boston, October 16.

James Carl Drake, Kerman, Calif., to Miss Rosalie Lord of Redwood, Calif., October 21.

Burr Burton Mosher to Miss Juliett Holmes Griffith, both of Brooklyn, October 26.

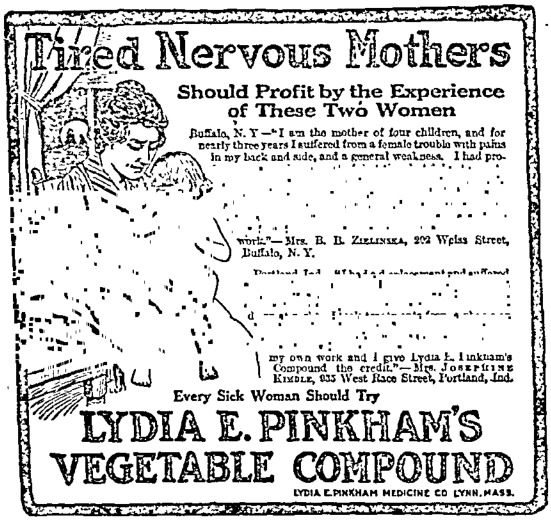
The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDED NOSTRUMS

Jacobs' Liver Salt.—This preparation was sold by the Jacobs' Pharmacy Co. of Atlanta, Ga., and, according to government reports, consisted largely of sodium phosphate, sodium sulphate, and common salt, incorporated with a dried mixture of washing soda, and citric acid. It was falsely and fraudulently claimed to be a remedy for headache, rheumatism, gout, gastritis, and sore throat. It was further misbranded, in that it was claimed to contain lithium phosphate in appreciable quantities, when, as a matter of fact, there was little, if any, lithium phosphate present. The company was fined $25 and costs.—[*Notice of Judgment No. 4992.*]

Lydia Pinkham's Vegetable Compound.—This widely advertised, alcoholic nostrum, put out by the Lydia E. Pinkham Medicine Co. of Lynn, Mass., was reported by the government to contain 17.9 per cent. alcohol, and 0.56 grains of solids to each 100 c.c., with vegetable extractive material present. It was falsely and fraudulently claimed to be effective as a remedy for falling of the womb, leucorrhea, inflammation and ulceration of the womb, for curing diseases of women and for all female ailments and affections, diseases of the bladder, and effective as a cure for dysmenorrhea, uterine tumors, diseases of the ovaries, etc., and as a preventive of miscarriage, "when, in truth and in fact, it was not." The company was fined $50.—[*Notice of Judgment No. 4997.*]



Tired Nervous Mothers

Should Profit by the Experience of These Two Women

Buffalo, N. Y.—"I am the mother of four children, and for nearly three years I suffered from a female trouble with pains in my back and side, and a general weakness. I had pro-

work."—Mrs. B. B. ZIELINSKA, 202 Weiss Street, Buffalo, N. Y.

my own work and I give Lydia E. Pinkham's Compound the credit."—Mrs. JOSEPHINE KIMBLE, 935 West Race Street, Portland, Ind.

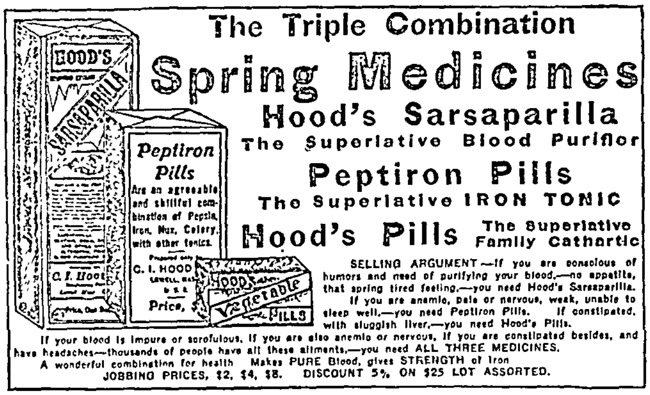
Every Sick Woman Should Try

LYDIA E. PINKHAM'S VEGETABLE COMPOUND

LYDIA E. PINKHAM MEDICINE CO LYNN, MASS.

Maguire's Extract of Benne Plant and Catechu Compound.—The J. & C. Maguire Medicine Co. of St. Louis sold this product, which contained over 39 per cent. of alcohol and 1/10 grain of morphin to each fluidounce, besides camphor, catechu and peppermint. The government charged that the claims made that it was a reliable specific for diarrhea, dysentery and cholera morbus, and a preventive of Asiatic cholera, were false and fraudulent, and further that the statement that it was "perfectly harmless" was false and misleading, in that it indicated that the article was composed of harmless medicinal agents as its principal and most active ingredients, when as a matter of fact, its principal and most active ingredient was a dangerous, habit-forming drug, morphin. The company pleaded not guilty, but the jury decided otherwise. The company then filed a motion for a new trial and the case having come on for retrial, the concern was again found guilty, and was fined $200 and costs.—[*Notice of Judgment No. 4988.*]

Hood's Sarsaparilla.—The C. I. Hood Co. of Lowell, Mass., was charged with misbranding "Hood's Compound Extract of Sarsaparilla." The federal chemists reported that the product was a mixture of alcohol (16½ per cent.) and water, containing about 0.90 per cent. of potassium iodid, 5.5 per cent. of sugars, 6.5 per cent. of vegetable extractives, which bore indications of the presence of sarsaparilla, licorice and a laxative drug resembling senna. The preparation was sold under the claim that it was a remedy for "scrofula," eczema, "cancerous humors," "catarrh," rheumatism, "female weakness," consumption, dropsy, varicose veins, and various other conditions. These claims were declared false and fraudulent, and the company was fined $50.—[*Notice of Judgment No. 4990.*]



HOOD'S

Spring Medicines

Hood's Sarsaparilla
The Superlative Blood Purifier

Peptiron Pills
The Superlative IRON TONIC

Hood's Pills The Superlative Family Cathartic

SELLING ARGUMENT.—If you are conscious of humors and need of purifying your blood,—no appetite, that spring tired feeling,—you need Hood's Sarsaparilla. If you are anemic, pale or nervous, weak, unable to sleep well,—you need Peptiron Pills. If constipated, with sluggish liver,—you need Hood's Pills.

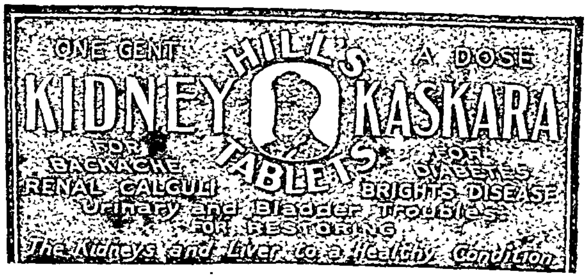
If your blood is impure or scrofulous, if you are also anemic or nervous, if you are constipated besides, and have headaches—thousands of people have all these ailments,—you need ALL THREE MEDICINES.

A wonderful combination for health Makes PURE Blood, gives STRENGTH of Iron

JOBBING PRICES, $2, $4, $8. DISCOUNT 5% ON $25 LOT ASSORTED.

Hyomei.—Booth's Hyomei Co. of Buffalo, N. Y., sold a preparation under the name of "Booth's Hyomei Dri-Ayr." Government chemists reported that the product consisted essentially of oil of eucalyptus, together with a small amount of resin-like solids and a mineral oil; also a little alcohol. It was sold under the false and fraudulent claim that it was a remedy for catarrh, asthma, bronchitis, hay-fever, and catarrhal deafness, "when in truth and in fact, it was not." The company was fined $10.—[*Notice of Judgment No. 4991.*]

Hill's Kidney Kaskara Tablets.—These tablets were put out by the W. H. Hill Co. of Detroit, Mich., and, according to government analysis, were an iron oxid, sugar-coated tablet carrying emodin, caffein, acid resin, magnesium carbonate and talcum. It was sold as a remedy for diabetes, Bright's disease, "consumption of the kidneys," renal calculi, etc., claims which were obviously false and fraudulent. The company filed a motion to quash the information, but the motion being denied, the company pleaded guilty and was fined $50.—[*Notice of Judgment No. 4993.*]



ONE CENT HILL'S A DOSE

KIDNEY KASKARA

TABLETS

FOR BACKACHE RENAL CALCULI

FOR DIABETES BRIGHT'S DISEASE

Urinary and Bladder Troubles

FOR RESTORING The Kidneys and Liver to a Healthy Condition

Hancock Sulphur Compound.—The Hancock Liquid Sulphur Co. of Baltimore was charged with misbranding its products, "Hancock Sulphur Compound," and "Hancock Sulphur Compound Ointment." Federal chemists reported that the former was a solution of calcium polysulphids and calcium thiosulphate, while the latter was an ointment containing petrolatum, with 0.91 per cent. of sulphur, 0.38 per cent.

ash (mainly lime), and carbolic acid (phenol). The liquid preparation was sold as a remedy for eczema, catarrh, sore throat, granulated eyelids, rheumatism, piles, blood diseases, etc., while the ointment was represented to be a remedy for eczema, skin diseases, all eruptions of the skin, scalp diseases, etc. The claims for both were declared false and fraudulent, and the company was fined $25 and costs.—[*Notice of Judgment No. 4994.*]

Palmer's Skin Whitener.—"Dr. Fred Palmer's Skin Whitener" was sold by the Jacobs' Pharmacy Co. of Atlanta, Ga. The Bureau of Chemistry reported that the product contained a poisonous and deleterious ingredient, namely, 7.85 per cent. mercury calculated as ammoniated mercury, mixed with a fatty base. It was sold under the claim that it was "absolutely harmless," which claim was false and misleading. It was also falsely and fraudulently claimed to be a remedy for all forms of eczema and skin eruptions. The company was fined $25 and costs.—[*Notice of Judgment No. 4995.*]

Grossman's Specific Mixture.—This preparation was sold by Wright's Indian Vegetable Pill Co. of New York City, and, according to federal chemists, was a mixture composed of two layers, the upper layer containing alcohol, water, opium and coloring matter, the lower, making up about 92 per cent. of the total mixture, being chiefly balsam copaiba and oils. The stuff was sold as a specific for the cure of gonorrhea, gleet, stricture, etc., and as a preventive of gonorrhea. These false and fraudulent claims brought about a fine of $100.—[*Notice of Judgment No. 4996.*]

Correspondence

"VACCINES IN INFLUENZA"

To the Editor:—The current comment in your issue of October 19 prompts me to call attention to the efforts of this laboratory and base hospital to do something specific for influenza. It was obvious from the first that the virus was an overwhelming one, and it was noteworthy that uncomplicated influenza was associated with leukopenia and that the complicating pneumonia raised the leukocytes very little, seemingly inadequately.

In casting about for a simple, efficient and safe means to raise the leukocytes, antiserum from recovered patients was used with some profit but without a great leukocyte reaction. We then prepared a serobacterin, using the serum of patients recovered from simple influenza and from influenza complicated by pneumonia. The bacteria used were two strains of influenza bacilli, one strain each of pneumococcus Type I and Type IV, one strain of hemolytic streptococci and one strain of nonhemolytic streptococci, all recovered from postmortems. This was administered subcutaneously, the leukocyte curve was watched, and it was found that there was a drop in leukocytes from six to twelve hours, followed by a rise at the end of eighteen hours, sometimes to 300 per cent. In no case was there any form of protein shock, and in only a few cases was there a slight local skin reaction. After the first few cases this bacterin has been given in doses of 100,000,000, 200,000,000 and 400,000,000, at intervals of twelve hours. In uncomplicated influenza, about forty cases, pneumonia has not occurred. Of nine pneumonia patients, two that were practically moribund have died and the rest have improved faster than patients similarly affected in the same ward. Some of this material has been supplied to Dr. J. H. Flexner of Louisville, who reports a very pronounced improvement and rapid fall of temperature after two doses. This gentleman also thinks that there has been pronounced improvement in cases of pneumonia.

We are still critical of this procedure and do not claim anything; but this letter is written because it would seem from the above mentioned "comment" that The Journal would be glad to have more information and because we should like to have others attempt this treatment in a critical spirit. It seems to be as simple and safe a means of producing hyperleukocytosis as can be imagined.

Herbert Fox, M. D.,
Major, M. C., U. S. Army. Camp Zachary Taylor, Louisville, Ky.

THE PHYSICIAN AND THE PROBLEMS OF RECONSTRUCTION

To the Editor:—I hope that no reader of The Journal failed to scrutinize the London Letter, Nov. 2, 1918, p. 1504.

As the close of the war draws near, the problems of reconstruction come more and more to arrest the attention of thoughtful citizens both at home and abroad. We have heard much in recent years of the physician in politics. Are we as a profession measuring up to the requirements of the situation or are we lagging behind our colleagues across the seas?

It is not ours to decide in full the future rôle of our profession. We need only to glance at Russia for the confirmation of this statement. In that troublous land of red revolution, the soviet government has definitely assigned the physician to a place with the bourgeoisie. In spite of his twenty-four hour day and his Sundayless week, the physician is to have no part in the dictatorship of the proletariat. In the purview of Lenine and Trotzky he is not a worker at all.

We scarcely anticipate anything like this in American politics, yet strange ferments are at work in our sociological brew. Just now, to read the *Congressional Record,* it would appear that we are menaced by the repudiation of the intelligensia. Certain members of Congress, during the recent discussion of a reserve for the Public Health Service, gave voice to a fear that medical men may achieve undue political influence. And one member—Mr. Sisson—saw fit to ignore the wise counsel of Burke, and to impeach the honor of a whole profession. It may be well, in these trying hours of war, when medical men are doing their best, to pause one moment to get the lawyer-politician's view:

> I will say that some years ago in my own state, when I was a member of the legislature, we had an appropriation for one of these funds for the purpose of taking care of the yellow fever epidemic if it should arise. Unfortunately, as long as that appropriation was in existence we had an annual yellow fever scare. As soon as that appropriation was withdrawn and no $50,000 or $75,000 was placed at the disposal of the health authorities, we had no more yellow fever epidemics except where they were real and genuine.
>
> That little experience has led me to believe that if you turn our good physicians—and we all have great respect for them—if you turn them loose, frequently they will find reasons sufficient, in their own mind, for calling into existence appropriations; whereas, if there was a limit placed upon it, a limit placed on the number of men that might be appointed, their activities would be very much lessened.

If our profession were placed wholly under government control, with salaries payable from the public funds, we should yet fall far short of congressional puissance, where a pull on your own bootstraps is all that is required to raise your salary.

Seriously, and to revert to the London letter, it is time to "get busy." I do not have reference to any movement for self-aggrandizement. We must do our part for the general welfare. Much of the "wisdom" of our teeming legislative halls is Poll-parrotism covered with cobwebs. The medical profession possesses a splendid reserve of trained intelligence which can be mobilized for service in legislative and executive positions. The modern education of the physician will prove, in the period of reconstruction, the most valuable asset of the state. It is not bookish exclusively. It commands a view of the fundamental sciences first-hand. The lawyer-politician, deficient as a rule in these vital elements of modern statesmanship, will take his place to the rear.

Finally, the physician's voice will be the voice of the larger humanity. He has never been a man of dollars. His heart beats the rhythm of that of the good Samaritan. He does not patent his inventions for human welfare and seek wealth from their exploitation. He has always carried his load of "charity practice"—a burden that properly belongs on the shoulders of the state. There is no man extant more competent to deal with rampant individualism; for his whole training and life work is a lesson of self-denial and sacrifice.

In the clear dawn of the new political day we shall perceive the outlines of the coming service-state, and shall behold the physician, pill-bags and scalpels for the moment aside, in the front ranks of the "forward looking" men of the time, doing service with the master-builders.

William Y. Ward, M.D., Ivanhoe, Texas.

TREATMENT OF INFLUENZA

To the Editor:—During the recent epidemic of influenza I saw a great number of cases in which one of the most prominent symptoms was hemorrhage from the nose, which lasted usually several days and was often profuse. What struck me in these cases was that none of the patients developed pneumonia and all recovered. . . . Does this bleeding give us a hint to employ bloodletting more frequently in cases in which pneumonia is suspected or beginning to develop?

Julius Martinson, M.D., New York.

To the Editor:—Having passed through a severe epidemic of influenza here we are sure that there have been some important things left unsaid concerning the nature and treatment of this disease. . . . The patient should breathe pure warm air, instead of cold air, which is the popular teaching at this time. With the patient extremely prostrated and perspiring and a further complication with bronchitis, it is certainly a contraindication to apply in the sick room the open air treatment. With the given pathologic condition, the cold air treatment will certainly prove a failure. The patient should breathe cold air in the febrile stage, but should avoid it by all means when that stage passes. The prostration requires rest in bed, and judicious medical stimulation and attention to dietetics.

W. E. Neiberger, M.D., Bloomington, Ill.

"TOMATO LEAVES AND DERMATITIS"

To the Editor:—In The Journal, Oct. 5, 1918, Dr. E. S. Lain of Oklahoma has a paper on "Dermatitis Lycopersicum Esculentum (Tomato Plant)." He calls the tomato "one of our most *harmless* and luscious vegetables." A few years ago there appeared in the *Correspondenz-Blatt für schweizer Aerzte* an observation of several cases of hematuria following the eating of tomatoes. Dr. Lain cites authors who attribute the dermatitis to individual susceptibility and even "anaphylactic reaction of a sensitized person." Is there not another possibility that would at the same time explain the cases of hematuria? The doctor says that the tomato belongs to the *Solanaceae*, nightshades, and mentions several other representatives of this group. But he forgot the most important one, the *Solanum tuberosum*, the potato. This, too, contains a poison in the eyes of the tuber that is removed in boiling. Every farmer knows how sensitive the potatoes are to the conditions of soil, of climate, rain and sun, place of growth, etc., as to development, taste, etc. The same is true of other peculiarities of other nightshades. The nettles, another representative, for example, may be handled with impunity in some places; in others, the slightest touch will have very painful consequences.

The following conclusions may be drawn: 1. The tomato is not under all circumstances "one of our most harmless vegetables." 2. The plant, as well as the fruit, may under certain not yet investigated conditions produce substances that are decidedly toxic to the skin and kidneys, and maybe to other tissues.

Jacques Holinger, M.D., Chicago.

DEVICES FOR DISABLED MEN

To the Editor:—I am sending to you the descriptions of some devices for men having lost one or both arms. They are founded on the last four years of experience among wounded and disabled men in England, and are the work of Dr. Arthur E. Shipley, vice chancellor of Cambridge University, who is now touring this country with the British Educational Mission.

The man who has lost an arm is usually sensitive about it, and does not like to attract attention, especially in public. Among other difficulties are those of cornering food on the ordinary plate. For this purpose Dr. Shipley has designed a plate with an overhanging lip and also a special plate that enables the patient to get the last drop of soup without tilting the plate, a feat that would be impossible for a one-armed man.

For convenience of commerce it has been suggested that the plates should be named, and "Unimanus" has been suggested (cf. Livy 35, 21 and 41, 21), but Dr. Shipley believes that it seems simpler and is certainly shorter to call them "manchot" plates.

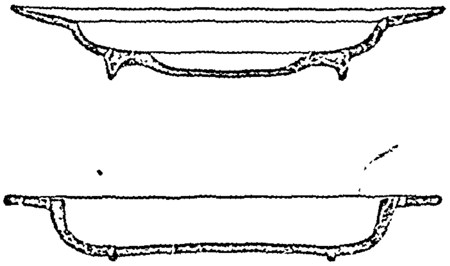


Fig. 1.—Cross-sections of plates devised for persons deprived of the use of one arm: The upper plate is a soup plate with a depression in the center from which the last two or three spoonfuls of soup can be easily removed. The lower plate is for solid food, and has vertical sides and an overhanging rim. Against this, pieces of meat or pudding can be pushed without any risk of their toppling over the edge.

The plates have been made in several styles, some as cheaply as possible, and all may be obtained of Messrs. Thomas Goode & Co., 19 South Audley Street, London. Messrs. Goode, who are solely financially responsible, have kindly consented to devote rather more than 20 per cent. of the profits to the Serbian Relief Fund.

When the patient has been unfortunate enough to lose both arms, he has not even the solace of reading, and the device illustrated enables him to turn over the pages of a book without calling in assistance. The disk which he holds in his teeth is made of rubber, and the shaft is aluminum with a light rubber tip.

If one may learn from the enemy, a good suggestion can be obtained from the fork that is specially made for the kaiser. The outside prong contains a cutting edge which transforms it into a combination knife and fork, and so obviates the use of the knife with the other hand. These would have to be made right or left handed.

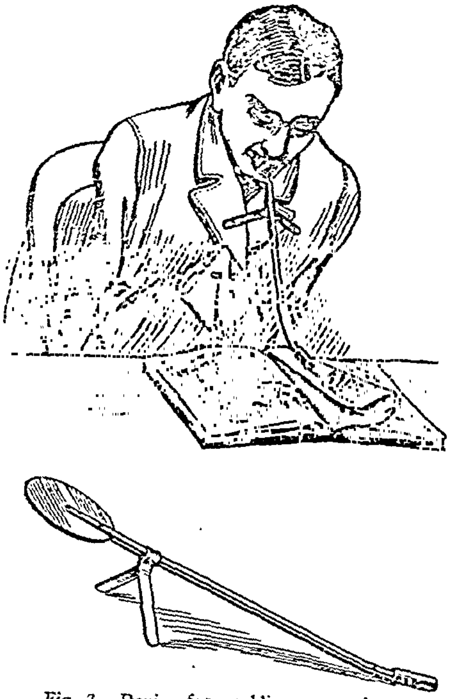

Fig. 2.—Device for enabling an armless person to turn the pages of a book.

I am sure there are many other devices which could render the life of the one armed, or otherwise disabled, much less difficult.

R. Tait McKenzie, M.D., Philadelphia.

AN INTERNATIONAL MEDICAL COUNCIL FOR THE RECONSTRUCTIVE PERIOD

To the Editor:—With the termination of actual hostilities, new problems will confront the medical profession in three main directions: (1) physical fitness; (2) the increased incidence of certain infective diseases, and (3) the insanitary, pestilential conditions resulting from the war.

The ideal method of preparing for this vitally important work would be by the creation of an international medical council to be composed of two or three representatives from each nation belonging to the Allies. The aims of such a body would be multiple, as follows: 1. To promote unity of purpose and action and to maintain friendly relations during postbellum days or the reconstruction period. 2. To exchange information bearing on the conditions, situations and methods, both medical and sanitary, of individual nations, and in this way facilitate the immense work to be done in combating disease, and in hygiene, sanitation and physical reconstruction. 3. Direct assistance could be rendered by one or more nations in unusually trying local situations resulting from devastations. In this connection America would be in a position to lend a strong hand, although we shall not enjoy an immunity from new and difficult medical, sanitary and other problems.

The door is already wide open and invites to professional thought and action in international terms. Shall we enter? The international council herein proposed could be inaugurated and conducted under the auspices of the American Medical Association or the American Red Cross or the Surgeon-Generals of the Army, Navy and Public Health Service, with the official sanction of the President of the United States.

J. M. Anders, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

MADURA FOOT (MYCETOMA) IN THE UNITED STATES

To the Editor:—1. Has the true "Madura foot" ever occurred in the United States? 2. Has it been determined how the mycetoma invades the human body?

J. H. M., Texas.

Answer.—1. Under the title "Madura Foot in America," Randolph Winslow says that up to October, 1917, the date of publication of his article, seven cases of Madura foot had been reported in the United States and Canada. Six were of the ochroid form and one of the melanoid form. Three occurred in Mexicans living in Texas, one in a French Canadian who had always lived in Canada, one in a young man born in Iowa, and one in a young woman living in Kansas. J. Homer Wright observed the only case of the black variety reported in this country in an Italian woman who had lived in America for several years. Sutton described two cases in which the *Streptothrix madurae* was found. This is believed to be the organism responsible for true Madura foot, though some authors include the ray fungus of actinomycosis as one of its causes.

2. It is believed that the organism always enters by way of a punctured or other wound, the foot being a favorite site of the disease on account of its exposure among those who go barefoot.

COMING EXAMINATIONS

Delaware: Wilmington, Dec. 10-12. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida (E): Jacksonville, Dec. 16-17. Sec., Dr. G. A. Munch, 1806 Franklin St., Tampa.

Florida (R.): Miami, Dec. 2-3. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Illinois: Chicago, Dec. 9-11. Mr. F. C. Dodds, Supt. of Registration, Springfield.

Iowa: Des Moines, Dec. 10-12. Sec., Dr. G. H. Sumner, Capitol Bldg., Des Moines.

Louisiana: New Orleans, Dec. 2-4. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Maryland: Baltimore, Dec. 10. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

Ohio: Columbus, Dec. 3-5. Sec., Dr. H. M. Platter, State House, Columbus.

Rhode Island: Providence, Jan. 2-3. Sec., Dr. B. U. Richards, State House, Providence.

Texas: Dallas, Nov. 19-21. Sec., Dr. M. F. Bettencourt, Mart.

Virginia: Richmond, Dec. 10-13. Sec., Dr. J. W. Preston, 215 S. Jefferson St., Roanoke.

West Virginia: Charleston, Nov. 19-21. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Massachusetts May Examination

Dr. W. P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, practical and written examination held at Boston, May 14-16, 1918. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 53 candidates examined, 41, including 1 osteopath, passed, and 12, including 7 osteopaths, failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Howard University	(1916)	76.9
Rush Medical College	(1917)	81.7
Johns Hopkins University	(1917)	81.9

Social Medicine, Medical Economics and Miscellany

REHABILITATION OF THE WOUNDED

A conference was held in Philadelphia, September 20, by the American Academy of Political and Social Science, at which the rehabilitation of the wounded was discussed. The nature and scope of the problem were presented by Dr. W. W. Keen. He pointed out that the fundamental difference between the surgical conditions during the Civil War and the present world war is our ignorance in 1861 and the enormous increase in our knowledge since that date. The almost virgin fields of battle during the Civil War held few bacteria; although tetanus was not common, it was deadly, killing nine of every ten victims. In the early days of the present world war it exacted a fearful toll of lives, exact figures of which can be given only after the war is over. As soon as there was a sufficient supply of the tetanus antitoxin, the mortality was close to nil. In the Civil War, compound fractures killed two out of every three, and amputations averaged over 50 per cent. mortality. Only 25 per cent. of the cases of compound fractures are now fatal, instead of 66 per cent. as in the sixties. Today the victory over infection is the reason for the greatly diminished number of amputations now done. Moreover, the mortality of amputations at present is low; in some series every one has recovered. While engineering and chemistry have done very much to develop modern sanitation, bacteriology has been the most important factor in this movement. Typhoid has been banished from the Army. In the entire army, numbering over 1,500,000 men at the end of December, 1917, there had been during the year 242 admissions to hospitals on account of typhoid, with eighteen deaths. During the corresponding period in 1861, when the Northern Army was being mobilized, there were about 9,500 cases of typhoid with less than one quarter of the strength of the present Army, with about 1,800 deaths. During the past year there was but one death ascribed to antityphoid vaccination among more than 1,500,000 men. This would seem to be an overwhelming testimony to the value of the method and to the fact that making it compulsory was essential to winning the war. The heart was first laid bare and sewed up for a stab wound twenty-one years ago (1897). Operations on the heart have now been done hundreds of times and have saved the lives of about half of those operated on. In the present war, missiles have been removed from the interior of the heart and even from the large blood vessels.

RECLAMATION OF MAIMED IN INDUSTRIES

Dr. Harry E. Mock, lieutenant-colonel, M. C., U. S. Army, speaking on the reclamation of the maimed in the industries, said that in warfare a number of men are bound to become disabled, but very few need remain so. The Medical Department of the Army began at the earliest moment to plan for the reclamation of the soldiers, and it is desired to make closer the cooperation between the Medical Department and the general public in the reconstruction and rehabilitation of the soldiers and sailors. During the past decade a new specialty has been developed in industrial medicine and surgery. In order to prevent waste, deformity and inefficiency, many industries have appointed a staff of physicians to look after men in the first-line trenches of the industrial army. Today one tenth of the workers of the nation are receiving the benefits of this work. Too often men injured in the industries are given positions without consideration of their fitness; if trained they could fill a gainful position. The most unfortunate among the injured and disabled in the industries are those not employed by the firm for which they worked. They must not only be cured, but trained for and given suitable positions affording them equal income to that received before their disability.

WHAT THE GOVERNMENT HAS DONE

Mr. James Phinney Munroe, vice chairman of the Federal Board for Vocational Education, pointed out that the colossal outpourings of wealth which the orgy of war has forced will possibly be redeemed in one generation by the spirit of saving which, with many other hard and salutary lessons, war has taught. Under the vocational rehabilitation act, the Federal Board for Vocational Education, made up, ex officiis, of the secretaries of agriculture, commerce and labor and the commissioner of education, and of three other members appointed by the President, is charged with responsibility for the placing back in economic life and, if need be, for the training of every soldier and sailor so far disabled in military service as to have become a beneficiary under the war risk insurance law. So long as that soldier or sailor needs daily hospital care or so long as he is adjudged fit to return to full or limited military service, he is the sole ward of the medical military authorities; but from the moment that he is discharged from military service, either because his disabilities are such as to preclude further Army service, or because he is relieved from such duty by the coming of peace, he becomes automatically a ward of the Federal Board of Vocational Education, and as such ward, has established rights which he alone and by his own free choice can surrender. After he has elected to receive training, the board, together with the War Risk Insurance Bureau, assumes not only his support and that of his dependents, should he have any, during the process of training, but also undertakes to follow him up after placement, and to give him reasonable opportunity for further training should the first venture prove ill suited to his capacities. The jobs that these men undertake will be theirs because they are fitted to take them. In this placement the board has the specific right under the law to ask the cooperation of the Department of Labor; it has the general right under the debt that we owe to these disabled men to seek the cooperation of every employer in every line of activity. The government will fulfil its sacred obligation to make these men as efficient as possible physically and also vocationally in the widest possible field of effective economic service.

TRAINING OF THE BLIND

Lieut.-Col. James Bordley, M. C., U. S. Army, discussed the training of the blind in the rehabilitation of soldiers and sailors. He emphasized the fact that in no phase of reconstruction are there more difficulties to overcome than in the training of the blind. The public has the conviction that the blind are industrially useless, forgetting the long list of distinguished blind statesmen, musicians, poets, warriors, merchants and inventors. A blind man can perform any operation except one in which judgment must be based on sight. The Surgeon-General of the Army, working in conjunction with the Surgeon-General of the Navy, has established in Baltimore, on a beautiful estate tendered the government for that purpose by Mrs. T. Harrison Garrett, a hospital training school for the blind sailors, soldiers and marines, and Congress has endowed the Federal Board for Vocational Education with money and power to supplement that training whenever necessary, and to provide the opportunity for employment. The American Red Cross has caused to be organized the Red Cross Institute for the Blind to supply such economic and social supervision as may be found necessary after the discharge of the blind by the various governmental departments. Vocationally, courses are classified as professional, agricultural, commercial, industrial, house work and blind shop work. Individual study of the men must determine into which of these classes they should go. The significance of the work is reflected in the hearty cooperation of every industry studied. If the blind man fails to make good, the employer will be relieved of all embarrassment by the removal of the blind man and his reeducation for another trade.

THE RÔLE OF THE AMERICAN RED CROSS

Mr. Curtis B. Lakeman, assistant to the Director-General of Civilian Relief, American Red Cross, said that the Red Cross will subordinate itself to government leadership and bend all its enthusiasm and resources to the promotion of the official plans and to the filling of such supplemental needs as may arise. Home service offers the channel through which patriotism and neighborliness combine to assist and protect the dependent wives, children, mothers and other relatives of soldiers and sailors. The Red Cross has in operation a special piece of war service machinery peculiarly adapted to assist in the after-care of the disabled soldier. Under the Department of Military Relief of the Red Cross there has been conducted also the pioneering research and educational work of the Red Cross Institute for Crippled and Disabled Men in New York, and the more recently established Red Cross Institute for the Blind supplementing the work of the Army Hospital at Baltimore. The home service organization is assisting the military medical authorities in obtaining essential data as to the previous history of the blind men, in explaining the government's plan to the family, and selecting the relative who will be taken to Baltimore by the Red Cross Institute and trained side by side with the blinded soldier.

READY-MADE FARMS FOR RETURNING SOLDIERS AND SAILORS

Frederic C. Howe, commissioner of immigration at the port of New York, pointed out that the United States Employment Service is a proper agency for carrying through the work of demobilization. All of the warring countries are emphasizing the necessity of returning the soldier to the land. In England, Australia and Canada the farm colony is being developed. Experts have submitted that the soldier will not take up an unbroken piece of land isolated from his fellows. Official commissions in England and Australia are developing plans by which the state will sell to the returning soldiers ready-made farms of from 3 to 30 acres which one man can cultivate. Farms are grouped as a community with educational, recreational and cooperative agencies for marketing and buying. Men are sold farms with a house, barn and sufficient capital on easy terms, the state advancing nine tenths of the capital to be repaid on long-term instalments. The experience of Australia and of Denmark demonstrates the success of this plan. In the United States such colonies should be located in New England, the Southern, Central and Western states, each adjusted to a special kind of farming. Tractors and farm machinery should be owned in common. Such a program involves no permanent burden to the nation. Such a comprehensive agricultural program is demanded by the drift of population to the cities, the growth of tenancy, and the exhaustion of the soil.

OPPORTUNITIES FOR EMPLOYMENT

Miss Gertrude R. Stein, employment secretary, Red Cross Institute for Crippled and Disabled Men, New York, said that the inception of the United States Employment Service has made every one ponder on what an ideal public bureau should be. In initiating an employment bureau for the handicapped, the Red Cross has the advantage of having the bureau a small one. No organization of this kind is truly valuable unless it is flexible. Employment work does not mean the mere securing of positions, but the securing of the chance to make a livelihood at congenial work, with the opportunity to make use of the best powers of the man. In New York there is an effective clearing house which is invaluable in widening the opportunities open to crippled men. A placement bureau for the handicapped must be more efficient than the average bureau or it will not live; it must have a file of satisfied employers who can be called on when the applicant seems suited for their particular job. It should be capable of securing a position for a teacher as well as for an elevator man, for a draftsman as well as for a lathe hand. An industrial survey of the opportunities for cripples in the city must be carried on in conjunction with the employment work. The whole system of placement is valueless unless it is properly followed up. Follow-up work in the factories should be discouraged; it is much better to advise the man and have him settle his industrial difficulties himself. By keeping systematic and full records together with a follow-up system a mass of valuable industrial facts is secured by one of the most economical and effective methods.

FURTHER DETAILS OF GOVERNMENT PLANS

Mr. T. B. Kinder, vocational secretary, Invalided Soldiers Commission of Canada, now on duty with the Vocational Educational Rehabilitation Division at Washington, stated that the United States goes farther than any other country in the care of its fighting men in that it provides that any man entitled to compensation as a result of his injuries may be provided after his discharge from service with a course of training at the expense of the government. In Canada every case is considered individually in the light of every factor with a possible bearing. This plan has been adopted also by the federal board at Washington in dealing with American soldiers. One of the most important factors in this connection is the man's educational history. His industrial history is also of great importance. The disabled man must have the will to succeed with his reeducation and successful placement. The man elects his course, but he must be assisted to select wisely and in the light of all the information with which his vocational advisers can provide him. A careful medical examination is made to determine the man's abilities, and medical and technical experts are consulted. In Canada, 1,347 men have completed courses of reeducation for new occupations; 1,868 are at present taking courses. More than 2,000 men are taking courses during convalescence. Many of the men receiving active treatment in bed are being trained vocationally. The large majority of men completing courses are in positions as good as were held before their service, and many are vastly better off. They are self-supporting, capable members of the community, fulfilling their duties in peace as they did in war. There is now before Congress a bill to provide for vocational rehabilitation for the injured in the industries and their return to employment. Of the men returned to Canada unfit for further military service only about 10 per cent. required reeducation for other occupations. An interesting fact also is that up to June 1, 1918, out of nearly 30,000 disabled men returned to Canada less than 1,500 had suffered a major amputation. The commission has proved the value of the occupation for mind and body of the men. It is disciplinary both for the disabled man himself, in that it prevented that moral and social deterioration always the result of prolonged idleness, and in the institution itself.

WHAT PENNSYLVANIA IS DOING

Mr. Lew R. Palmer, acting commissioner of the state department of labor and industry, said that 50,000 jobs are open and waiting in Pennsylvania for disabled soldiers returning from France. Industrial accidents in this state in two and a half years, ending July 1, have crippled more men than were crippled in the Canadian army in four years of war. Pennsylvania was the first state in the Union to take steps toward providing employment for the blind and the crippled after the war. Seven months before Congress adopted the rehabilitation act, Pennsylvania, through the department of labor and industry, submitted questionnaires to 900 industrial plants to ascertain in what capacity each plant could employ the disabled war veterans. Of the 50,000 jobs awaiting the crippled heroes, 47,000 are in industrial work; 900 are clerical; 16 are in agricultural lines, and 1,200 are miscellaneous. The number of amputations due to industrial accidents in this state were 3,798 in two and a half years, while in the four years of war Canada's army had only 1,200 amputations. In Pennsylvania, 1,157 eyes were lost as the result of industrial accidents, while up to last spring only thirty-four Canadian soldiers had been blinded.

EMPLOYMENT OF DISABLED SERVICE MEN

Mr. Frederic W. Keough, of the National Association of Manufacturers, pointed out that manufacturers will go the limit in appreciation and care of the injured. Bringing the physically unfit and disabled men to an irreducible minimum is a national obligation. If disabilities make it inadvisable for a man to follow his former occupation, he should be fitted for a new occupation by appropriate training. The greatest number of openings undoubtedly are in the clerical fields. In France, blind soldiers have been trained to take dictation on a special machine and to transcribe their notes rapidly and accurately. Among the industries open to disabled men are the plate glass, machinery building, boiler-making and printing. In the underwear industry many firms have offered to take disabled men, one firm even offering to employ them up to one sixth of the operating force. For men who have suffered the loss of their arms, the chemical industry is particularly inviting. The large number of processes that require little manual labor but careful watching make it possible to employ men lacking both arms. One chemical firm in Maryland has offered to take fifteen such men and train them to watch processes. An Ohio chemical firm has made a similar offer. An electrical manufacturer in the United States has discovered that blind men can be employed with great success in winding armatures. Many and varied industrial opportunities have been offered, proving that no industry is entirely closed to these workers. It has been the experience of firms already employing disabled men that they are so keenly appreciative of the opportunity offered that their spirit of willingness more than makes up for the disability. The matter, however, has been most aptly summed up by a New England firm, which says that the crippled workers in its employ are so satisfactory that the firm has often wished it had more such employees.

Book Notices

Modern Dentistry. By Joseph Head, M.D., D.D.S., Dentist to the Jefferson Hospital, Philadelphia. Cloth. Price, $5 net. Pp. 374, with 309 illustrations. Philadelphia: W. B. Saunders Company, 1917.

The author has attempted to cover most of the different branches of dentistry, a difficult thing to do, since no one individual can be equally well informed on such diversified subjects. The chapter devoted to the care of the teeth is well worth reading, and the clear pictures illustrating the proper methods of brushing and otherwise caring for the teeth will be helpful to those who have not given this subject sufficient attention. Some of the conclusions arrived at by the author as a result of his research work are rather startling. For instance, he goes into great detail and has constructed elaborate instruments to prove that decalcified enamel can be rehardened. One cannot but admire the writer's enthusiasm, although his conclusions will hardly be accepted without further verification. The author states that if the pulp of a tooth is destroyed mechanically under a local anesthetic and the root canals filled, the dentin will still live and be nourished by the peridental membrane. This is not in accordance with biologic principles as understood by scientists; if true, the works of Black and others will have to be completely revised.

Under the head of vaccines in the treatment of mouth infections, the author cites some remarkable cures of secondary conditions following their administration. One cannot but wonder if the writer has not attributed too much virtue to the vaccines and not enough to the surgical removal of the primary mouth infection.

There are chapters on filling teeth, orthodontia, prosthetic appliances, roentgenography, etc. The pictures made from roentgenograms have been fairly well selected, and they are clearer and their outlines more distinct than is usually seen in such publications. The illustrations are numerous and excellent.

The Action of Muscles, Including Muscle Rest and Muscle Reeducation. By William Colin Mackenzie, M.D., F.R.C.S., F.R.S., Member of the Council of the Anatomical Society of Great Britain and Ireland. Cloth. Price, $3. Pp. 267, with 99 illustrations. New York: Paul B. Hoeber, 1918.

This book will be of especial value to those having in charge the reconstruction of the soldier who has suffered injury to muscles with loss of function. So impressed is Mackenzie by the importance of scientific rest and reeducation of muscles that he advocates having as a principal feature in every orthopedic institution a department of myology. Massage and electricity should be entirely subsidiary agencies. As one reads his book one is convinced of the ignorance of the ordinary surgeon and of many orthopedic surgeons as to these important matters. The principles underlying the treatment of weak muscles are clearly set forth, with details for the application of these principles in the care of separate muscles. Diagrams and other illustrations aid one to understand the technic.

Liability of Insurer for Medical Aid Depends on Notice

(American Indemnity Co. v. Nelson et al. (Texas), 201 S. W. R. 686)

The Court of Civil Appeals of Texas reverses a judgment for $150 against the indemnity company that the parents of a boy obtained for the expense of medical services rendered by a physician during the first week after the boy had been injured in an employment in which the employees were insured by the company under the Workmen's Compensation Act of Texas of 1913, because there was no evidence that any notice of the boy's injury was given to the company before the physician was employed by the boy's parents to treat him, or that the company knew of his injury during the time he was being treated. The court says that it seems to it that this statute is plain and unambiguous, and that by its plain terms no association or insurance company organized or acting thereunder in insuring the employees named in the act can be held liable for medical aid furnished an injured employee unless the insurer is given reasonable notice of the injury before such medical aid is furnished. The obvious purpose of requiring this notice to be given is to give the insurer an opportunity to select and contract with a physician of its own choosing. The final result of an injury to an employee and the consequent amount of the insurer's liability may often depend on the medical treatment given during the first week of the injury, and charges for such treatment might be much less when done under a contract made by the insurer than when left to be determined by evidence, which is often conflicting, of the reasonable value of the medical treatment. For these reasons it seems to the court entirely proper that before an insurer is made liable for money paid or incurred for medical aid furnished an insured employee, the insurer should be given an opportunity to furnish such aid. But whatever may be the reason for the statute the court thinks its language is plain and unambiguous, and it must be construed as making the liability of the insurer dependent on failure to furnish medical aid after reasonable notice of the injury. Statutes of other states similar to this one have been so construed. But the majority of the court does not think the right to sue for money paid or incurred for medical services rendered an injured employee is given by the statute to the employee only, but it takes the view that any person who pays for such medical aid or incurs liability therefor may sue the association and recover the amount so paid or incurred.

Performing Necropsy to Ascertain Cause of Death

(Woods v. Graham et al. (Minn.), 167 N. W. R. 113)

The Supreme Court of Minnesota, in affirming an order sustaining a demurrer to defendant Graham's answer, holds that it was no defense to an action to recover damages caused by a necropsy performed on the body of the daughter of the plaintiff, without the consent of the next of kin, that the defendant, as the attending physician, was unable to ascertain the cause of death and performed the necropsy for that purpose so as to be able to give a certificate, as required by law, stating the cause of death. The court says that the plaintiff brought this action to recover damages for a necropsy performed without her consent on the body of her daughter by defendant Graham. His answer admitted performance of the necropsy without the consent of the plaintiff, a widow, and set up as a defense that he was the county physician; that he attended the girl as a charity case in her last illness, and that a necropsy was necessary in order to ascertain the cause of death; that the undertaker in whose hands the body had been placed applied to him to execute the medical certificate required by law, stating the cause of death, and that he was obliged to perform the necropsy in order to be able to give this certificate. The answer alleged that the defendant made the necropsy in good faith, for the purpose of ascertaining the disease or injury which caused the death, and solely that he might be able to make and subscribe such certificate and in order that a permit might lawfully be issued for the burial of the body; it was further alleged that the necropsy was made in a decent and scientific manner, and that no incisions were made that were not necessary in order to ascertain the cause of death.

It was conceded that the plaintiff's consent to the necropsy was not obtained or asked for, and that she had no knowledge thereof until after the necropsy was performed. The defendant claimed freedom from liability on the ground that it was necessary to have the necropsy in order to discover the cause of death and to be able to give the certificate required by Section 4652 of the General Statutes of Minnesota of 1913. That section requires the undertaker to obtain and file a medical certificate subscribed by the attending physician, stating the disease or injury causing death, with contributory cause or complication, etc. Section 4654 provides that a burial permit shall not be issued except on the filing of a proper certificate of death. Section 4658 provides that no body shall be interred until a proper certificate of death has been filed and a permit issued. Section 4662 provides that any person wilfully refusing to perform any duties imposed by the act is guilty of a misdemeanor.

The supreme court agrees with the trial court that the answer stated no defense to the action. The sections of the statute referred to do not in terms authorize a necropsy to ascertain the cause of death. This court is unable to hold that they authorize it by implication. Section 8745 makes it a gross misdemeanor to dissect the dead body of a human being, except in cases "specially provided by statute," or where the direction or will of the deceased authorizes it, or where the coroner authorizes it, or where the "husband, wife, or next of kin, charged by law with the duty of burial, shall authorize dissection for the purpose of ascertaining the cause of death, and then only to the extent so authorized." It cannot be held that this was a case "specially provided by statute."

No Injunction Against Unlawfully Practicing Medicine

(Crowder v. Graham (Texas), 201 S. W. R. 1053)

The Court of Civil Appeals of Texas holds that an order granting a temporary injunction in the suit of plaintiff Graham, as county attorney, to restrain defendant Crowder, a masseur, from unlawfully practicing medicine, must be reversed and judgment rendered vacating the order and the writ issued thereunder. The court says that it is of the opinion that the offense of "unlawfully practicing medicine," within the meaning of the provisions of Chapter 6, Title 12, of the Penal Code, is not a "trade, business, or occupation injurious to the health of those in the neighborhood," within the meaning of Article 694 of the Penal Code and of Article 148 of the Code of Criminal Procedure, authorizing the issuance of a writ of injunction after indictment or information has been filed alleging such offense. Article 694 prescribes as a punishment a fine of not less than $10 nor more than $100, while by Article 756 the punishment prescribed for the unlawful practice of medicine is a fine not less than $50 nor more than $500, and by imprisonment in the county jail for a term not exceeding six months; and those articles are in separate and distinct chapters of the statutes. The acts denounced as an offense in Article 694 constitute a public nuisance under the common law. The court is of the opinion that such is the only character of acts made an offense by that statute, as indicated by those acts described in other articles of the same chapter, which are specifically made criminal offenses and specific penalties are prescribed therefor, and that by Article 148 of the Code of Criminal Procedure it was not intended to authorize the issuance of writs of injunction to restrain the commission of such an offense as the unlawful practice of medicine. It is well settled that, in the absence of some statute specifically authorizing it, an injunction will not lie to restrain the violation of a penal statute, simply because the act enjoined is denounced as an offense, but that an injunction will lie to restrain the act, even though it is an offense, if it constitutes a public nuisance under the common law. The court is of the opinion, however, as indicated above, that the business followed by the defendant would not constitute such a public nuisance.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Eighth Annual Session, held at Philadelphia, Sept. 23-26, 1919

(Continued from page 1608)

New Medical Conditions, and Developments in Previously Recognized Complaints, Due to War Emergency

Dr. J. M. Anders, Philadelphia: The enhanced virulence of the streptococcus is the most important problem in dealing with infections of soldiers in the present war. The mortality rate in empyema due to *Streptococcus hemolyticus* is not less than 75 per cent., while in the form due to the pneumococcus, recovery is the rule. The most approved treatment is aspiration, repeated as often as necessary, and intrapleural disinfection with neutral solution of chlorinated soda. Prophylactic vaccination against pneumonia with the hemolytic streptococcus and pneumococci of Types I and II is advised. In the various forms of disordered heart action in soldiers, the patient must not be permitted to entertain the notion that he has a diseased heart. In the higher incidence of tuberculosis in certain foreign countries, the cause in the majority of cases apparently is endogenous, while a considerable percentage may be attributed to primary exogenous infection. According to Sergent, the most trustworthy physical signs of a lesion of the parenchyma of the lung are "dulness, hemoptysis, increased fremitus, 'clicks,' and a veil or shadow at the apices, fixed, not modified by cough with striae and fly spots on the plate." In my view, the examiner of recruits should rely quite as much on a history, presence or absence of fever, the pulse, detection of bacilli in the urine and of antibodies in the blood, as on the physical signs and roentgen-ray findings. Also tuberculous lesions should be searched for in all other organs of the body besides the lungs. The tests to be applied to keep the latent cases of tuberculosis out of military service cannot be too stringent.

DISCUSSION

Dr. Thomas McCrae, Philadelphia: Dr. Anders draws attention to the presence in the Army of problems other than surgical. The cases of disturbed heart action are the bane of every medical man in the Army. Infection plays a very small part. This is true also of internal gland secretion. The overwhelming factor is the nervous element. There is nothing concerned with the disordered heart action as seen in the Army that one does not see in civil life. Dr. Anders suggests the possibility of aggravation by the strain of war; many of the men never get to war. One very big problem is the part played by tobacco. I think it is agreed that while tobacco may not have been the original cause of the condition, it plays a large part in aggravating it when once present, and it is a very difficult problem to handle in the Army. When the quantity of tobacco used by a man amounts to forty cigarets a day it must be realized that he is taking a drug that poisons him. The question of the proper allowance of tobacco to men with disturbed heart action should be considered. Regarding the question of a certain number of men being sent back from the French front line with a diagnosis of tuberculosis when only a certain proportion had the disease, I think there is no reflection on the diagnostic ability of the French surgeons. It is to be remembered that all these men had lost weight, and the majority had acute bronchitis with bloody sputum; signs were probably present throughout the lungs. To say whether or not they had acute tuberculosis passes the ability of any man up in the front and of the man in the base hospital until he has time to observe them.

Coordination of Laboratory and Clinical Researches in Pneumonia

Dr. S. Solis-Cohen, Philadelphia: See abstracts in The Journal, June 1, 1918, p. 1635.

DISCUSSION

Dr. David Riesman, Philadelphia: In no disease is the close cooperation of laboratory workers and clinicians more opportune than in pneumonia, the most fatal and most serious infectious disease we have to deal with in this climate. I cannot feel that quinin is a specific in pneumonia. Of serums we have only one that is of value. The problem of pneumonia must be attacked more from the point of prevention than hitherto. From the standpoint of a sanitarian and a physician, one of the most important discoveries is that a healthy carrier may spread the disease.

Dr. George D. Heist, Philadelphia: In our research work we found that the serum of one man who had received 5 and sometimes 10 grains of quinin dihydrobromid every three hours over a period of a number of days killed pneumococci with great regularity after an exposure for twenty-four hours. In other cases the pneumococci were very decidedly inhibited in their growth. The bactericidal elements in the serum was proportionate to the quantity of quinin received by the patient. The dihydrobromid was the most active salt. The serums of recovered patients and of those who received no quinin showed no bactericidal action. Dr. Cohen had long pointed out to us that the patient with pneumonia does not feel the quinin as does one not having the disease. This observation was confirmed by me in our work.

Dr. S. Solis-Cohen, Philadelphia: Quinin has never been put forth as a specific in pneumonia. Midway between the expectant treatment and treatment by serums and bacterins is the definite method of the treatment by quinin: quinin given in a definite way and for a definite purpose. In my own experience no other medicinal treatment is equal to it.

Laboratory Methods: Their Value and Practicability in General Medicine

Dr. M. Howard Fussell, Philadelphia: I wish to plead for accurate diagnosis, possible only by history taking, thorough physical examination, and routine laboratory examinations. The man does not live who can guess at conditions and not sooner or later take a cropper. I would advise the man not educated in the more accurate diagnostic methods to associate with himself a young man who can do this routine work for him.

DISCUSSION

Dr. Henry Rhea Douglas, Harrisburg: A boy, aged 9 years, was treated for years for an eye condition accompanied by anemia and glandular enlargement. Subsequent laboratory examination revealed a + + + + Wassermann reaction.

Dr. H. W. Mitchell, Warren: Laboratory study practically settles all doubt in diagnosis in a large group of patients admitted to the hospitals for the insane.

Dr. Paul G. Weston, Warren: I would enter a plea for the more frequent use of lumbar puncture for diagnostic purposes. The technic is simple and does not require extraordinary skill. The chemical analysis of the blood should accompany urinalyses.

Dr. Charles Rae, York: To be borne in mind in making our diagnoses is the relative unimportance of negative findings. I would emphasize the importance to every man with a large practice of having a trained assistant to do his laboratory work.

Some Drug Eruptions

Dr. M. B. Hartzell, Philadelphia: A large number of drugs produce eruptions, but relatively few affect all individuals. The same drug does not always produce the same form of eruption. The iodids usually produce an acneiform eruption, but may cause more serious conditions; the same is true of the bromids. The hypnotics frequently produce eruptions of varying character; those resulting from the administration of barbital are often accompanied by severe itching and burning; a chronic pruritus may be a symptom of opium addiction. The preparations of arsenic occasionally produce herpes zoster; they cause a variety of keratosis possibly followed by epithelioma. Arsphenamin sometimes causes a violent dermatitis with symptoms of nephritis. In the presence of an unusual form of eruption, the possibility of its drug origin should be considered.

DISCUSSION

Dr. Julius H. Comroe, York: In one case the administration of 270 grains of potassium iodid, three times a day, in ascending doses, for almost three months failed to produce the least suggestion of a rash, yet in another case the administration of 3 grains developed a most intense rash. Rather than advise routine ascending doses, it would seem better practice to treat each case as an individual entity, and on the slightest evidence of a rash, either diminish or interrupt the dose; also by giving more attention to the emunctories during the administration of bromids, iodids, etc., we should be meeting in a better way the prophylactic requirements of the problem.

Follow-Up System of the Pennsylvania Department of Health for Former Tuberculous Patients

Dr. Karl Schaffle, Harrisburg: The follow-up system of the Pennsylvania Department of Health for the tracing and reporting of patients discharged from the state sanatoriums and dispensaries consists in actual face-to-face inquiry and inspection of the former patient by the dispensary nurse who has been intimately acquainted with his physical condition and economic status during his enrolment as an active case. One hundred and thirty nurses carry on these special investigations throughout the state in addition to their supervision of the home care of those in regular attendance. Such follow-up visits are made for a period of two years after the patient's discharge, at intervals of six months.

DISCUSSION

Dr. B. Franklin Royer, Harrisburg: In dispensary and sanatorium treatment some such follow-up system must be relied on to prove the end-results. The campaign of tuberculosis is almost wholly an educational one; we aim to teach the individual how he should live in order that Nature may effect the cure. After all, it is a question of food and open air, rest when needed and exercise when needed. It is a careful direction of the habits of life which results in the cure of the individual once infected, and it is a question of teaching that individual such methods of living that he will not infect the children who surround him. It will take from twenty-five to fifty years of just such an intensive educational drive in order to reach a point where our final statistics will show.

Dr. Charles H. Miner, Wilkes-Barre: One part of the work in the dispensary is of special interest today, and that is to look up the soldiers who register and who have been rejected by the draft boards and the Army camps for tuberculosis. At this time, of course, that is of greater importance than almost any other feature of the tuberculosis work of the department because many of these men have never suspected that they had any trouble of that kind and they especially should be sought out and urged to secure some advice and treatment. Many of them are very skeptical about having any trouble and are patients who need the advice of the nurses and the physicians at the dispensary.

Dr. Karl Schaffle, Harrisburg: We have received through the cooperation of Major Murdock, who is in charge, the names of more than 1,200 draftees rejected by selective service boards throughout the state, and we write a letter to each man so rejected telling him that we have received confidential information that he has been rejected on account of tuberculosis and advising him to seek treatment through his family physician, or through a private institution if he can afford to do so, or, if not, through the department by means of its dispensaries and sanatoriums. We follow up that letter by sending a dispensary nurse from the dispensary nearest the man's home to call on him personally, and to explain the matter at great length, and to urge that he seek treatment because practically all of these cases are the early cases, cases that are curable. We have the same difficulty, however, that we have with the average incipient case. A great many of these persons refuse to believe they have the disease.

Present Status of the Treatment of Syphilis

Dr. Jay F. Schamberg, Philadelphia: There are three recognized drugs in the treatment of syphilis—arsphenamin, mercury and the iodids. Arsphenamin is generally recognized to be the remedy of paramount value. Its effect on symptoms is due to the fact that it has a powerful destructive effect on the spirochete and that it may be administered in large dosage. Arsphenamin is fifty times less toxic for experimental animals than is mercury. Arsphenamin likewise has a roborant or tonic effect which mercury does not possess. The spirochete is vulnerable to arsphenamin and to mercury. The iodids do not appear to have direct destructive influence on the spirochete. Wechselmann has warned against the use of mercury precedent to the use of arsphenamin, on the grounds that most of the arsphenamin fatalities are due, in large part, to renal insufficiency, and that in the majority of cases it was mercury that damaged the kidneys. My belief is that the use of three inunctions of mercury a week is a valuable measure to associate with the use of arsphenamin, particularly in the primary and secondary stages of syphilis. No one is in an authoritative position today to state how long the treatment of syphilis should continue. Too often the physician will cease treatment after a single series of arsphenamin injections and perhaps a course of mercury, because the Wassermann reaction has become negative. Experience proves that such a course usually requires the later resumption of treatment, with valuable time lost. While it is difficult to prescribe any routine formula, we may at least indicate an irreducible minimum of treatment. Before any patient with syphilis is discharged from observation, a diagnostic spinal puncture should be made.

DISCUSSION

Dr. Francis X. Dercum, Philadelphia: Arsphenamin has been used extensively at the Jefferson Hospital, and I have used it in the exudative form and in the form represented by tabes and paresis. Our experience with regard to paresis has been that not infrequently we had remissions. I am glad to hear Dr. Schamberg say he uses inunctions every other day. In the old days they were used every day. I use half a dram of mercury every other day with arsphenamin and feel my way. I think we use the drug too frequently. There ought to be an interval of ten days or two weeks. Very frequently I allow an interval of two weeks.

A Method of Tracheotomy Without Loss of Blood

Dr. Donald Guthrie, Sayre: The low operation of trachetomy, unless there is an enlargement of the thyroid, is the more suitable for all cases—even the struggling child. The child is wrapped in a blanket or sheet to control its struggling and placed on the table. A pad of some sort is put under the shoulders, and the head is hung over the end of the table—steadied by an assistant. The operator stands on the right hand side of the table and, steadying the skin with the left hand, makes an incision in the midline of the neck from 1½ to 1¾ inches long. The skin and the superficial fascia are incised and the wound is held open by a pair of catspaw retractors which should not be more than an inch in breadth. When the deep cervical fascia is cut, the parallel branches of the anterior jugular veins are seen in the wound. The retractors are reset to pull these veins aside, and the sternohyoid and sternothyroid muscles are separated by blunt dissection. If care can be exercised during this step of the operation, the muscles can usually be separated without injury to the thyroid ima beneath. The retractors are again reset, the left blade holding aside the skin, the fascia and the two muscles, and the right blade the skin fascia, the muscles and the thyroid ima vein. This exposes the trachea to view. It is incised, the head is straightened, and the tracheotomy tube inserted. This method has been employed fourteen times in all types of cases.

DISCUSSION

Dr. George P. Müller, Philadelphia: From my own thought and experience I mostly disagree with Dr. Guthrie. Surgeons know the exact anatomy of these structures. They are used to dealing with hemorrhage and do not have the slightest fear of it. It does not matter to a surgeon whether he does a high or low tracheotomy; but it seems to me that it is by no means as easy for the general practitioner to do the low operation as the high. When it comes to operation in emergency in a patient with diphtheria or membranes, or other choking condition in the upper air passages, the high operation is preferable. A low tracheotomy is dangerous if suppuration results, as it is liable to travel into the mediastinum.

Anatomic Incision for Groin Surgery

Dr. J. Norman White, Scranton, Pa.: An incision 3 inches long, three-fourths inch external to the spine of the pubes, commencing at and at right angles to Poupart's ligament and extending toward the umbilicus gives access to the inguinal canal and round ligament, and extension downward and slightly inward exposes the femoral ring. If a femoral has been mistaken for an inguinal hernia, or vice versa, no new incision is required nor extensive prolongation of the one already made. The wound never fills with fluid, as often happens with other incisions. No blood vessels need be tied because none are cut. The incision is parallel rather than across the blood and lymph vessels. Leaving the blood and lymph supply intact infection is less frequent. Any operation in the inguinal region can be performed through the one incision including appendectomy.

DISCUSSION

Dr. T. Turner Thomas, Philadelphia: I have tried this incision in about a dozen cases. It does not give the same free and easy exposure of the canal as does the ordinary oblique incision. The novice would have trouble in locating the external oblique ring, but the experienced operator would not. Very few, if any, blood vessels are divided. There is enough advantage in the small number of blood vessels divided to warrant using this incision in spite of the little restriction in the exposure of the field.

Thoracic Surgery

Dr. George P. Müller, Philadelphia: Pierre Duval has shown that the exposure of the lung and the removal from it of a foreign body is as safe as most other major operations, and not only enables us to remove the bullet but also to clean the pleural cavity of its contained blood clot. Shortly after the receipt of the injury, when reaction has occurred, ether is administered by the open method (an endotracheal apparatus is not necessary), and an incision 9 or 10 inches long is made over the fourth or fifth rib. About six inches of the rib is then removed, and after cutting the intercostal membranes the pleura is carefully separated with the fingers above and below for some distance, to mobilize it. The pleural membrane is then rapidly divided the full length of the opening and a rib spreader is placed in position rapidly and sprung open. The lung is then taken by a pair of grasping forceps and pulled to the wound. If these maneuvers are done rapidly the mediastinum is steadied before the pneumothorax has had time to work injury to the circulation. The lung can then be drawn out onto the chest, the bullet easily felt, the lung incised over the bullet, which is removed, and the incision closed by one or two fine catgut sutures. Blood clots are scooped out, the cavity is gently mopped and disinfected, if thought necessary, by ether (Duval) or perhaps by neutral solution of chlorinated soda. The lung is then replaced but still steadied by the grasping forceps and the pleura is closed. The muscles are next pulled together with catgut mattress sutures and the skin is sutured with silkworm gut. No drainage should be introduced. Finally, the pneumothorax is emptied by aspiration. If it is determined not to search for the bullet, aspirate the pleural cavity on the slightest suspicion of the onset of infection, and if coverslip smears confirm suspicion, the chest must be opened and drained.

DISCUSSION

DR. SAMUEL J. MELTZER, New York: About eight years ago I constructed a simple apparatus for intratracheal insufflation for Dr. Carrel. I have seen many of his experimental dogs in which the thorax was transversely opened widely—double pneumothorax. These dogs recovered without having had an infection. In the course of the last year, I demonstrated to several hundred military officers anesthetized and curarized dogs with the chest wide open. The entire heart was exposed to full view. The animals were kept alive and with normal blood pressure by pharyngeal insufflation. I have often demonstrated a fact of practical importance, namely, that if artificial respiration was sufficient, the heart could be handled freely with impunity; but even a slight touch of the heart ofen led to fatal fibrillary contractions if the artificial respiration was suspended or was insufficiently executed.

Operation: Designed to Permit Future Childbearing, Without Complications

DR. JOHN COOKE HIRST, Philadelphia: My experience with this operation comprises a total of 141 cases. Not all these women were of child bearing age, though the majority were, but the same technic was used in all of them. I have seen no primary failures, and none of the cases have required a second operation, as far as I know. The result as to subsequent delivery: Of forty-nine known cases, seven have become pregnant. Of these, two miscarried, due probably to overexertion, of which there was a definite history in each case. Five went through labor at term, one of them twice. Four of the five, including the one with two deliveries, show a very normal looking anterior vaginal wall, the surgical result is good, and they are symptomatically well. In the fifth case there is a measure of recurrence. The anterior wall sags considerably, but nothing like the extent of the previous cystocele. The patient is symptomatically well. Whether the cystocele will increase in size, it is as yet too early to determine. It seems to be stationary up to the present.

(To be continued)

INTERSTATE ASSOCIATION OF ANESTHETISTS

Fourth Annual Meeting, held at Indianapolis, Sept. 25-27, 1918

(Concluded from page 1607)

What the Expert Anesthetist Should Be

DR. A. S. MCCORMICK, Akron, Ohio: A specialist in any branch of medicine or surgery must have the foundation of a proper academic and professional education, with considerable general experience and a great deal of special study and practice of his chosen branch. Aside from this he must have a liking and aptitude for his specialty if he is to succeed in it. Furthermore, he must devote his time exclusively to his particular line of work. In anesthesia these requisites would comprehend a collegiate course, followed by four years at an A 1 medical school, which gives proper attention to anesthesia in its curriculum and clinics, an internship in a hospital in which anesthesia is under the control and supervision of experts, then postgraduate study in various centers where the latest methods of anesthesia may be studied and tried out, followed by intensive practice of the specialty in some chosen community in which there is an opportunity for becoming connected with several prominent surgical teams or hospitals in which surgery is on a distinct plane of excellence. Having achieved this much, the anesthetist owes it to himself to maintain an equipment of apparatus that will enable him to meet the anesthetic requirements for any surgical procedure with safety and comfort to the patient and satisfaction to the operator.

The Anesthetist on the Hospital Staff

DR. ISABELLA C. HERB, Chicago: In accepting a staff position at any hospital, the anesthetist should assume all the duties and responsibilities applying thereto with a sense of their seriousness, for life itself is being entrusted into his keeping. As a member of the staff he is virtually a consultant, and if he is at all competent he will be in a position to advise with regard to the proper preparation of all patients for anesthesia and operation. He must know how to care for patients postoperatively so that no matter how hazardous or desperate the operative procedure or how difficult the anesthesia, the patient's convalescence can be assured and protected from untoward incidence of shock, hemorrhage, pneumonitis or toxemia.

If he is staff anesthetist to a teaching hospital, he should constantly be working out the newer problems in his specialty and utilizing the interns and nurses at his disposal for the technical phases of this clinical or research activity. As a member of the staff, the anesthetist should take an especial pride in the anesthetic and operative records of his hospital. If the institution provides the opportunities and facilities for giving postgraduate instruction in anesthesia, the staff anesthetist should develop himself to the point at which he can handle this additional responsibility with credit to himself, his hospital and with satisfaction to his students. The staff anesthetist should participate as much as possible in the experimental phases of hospital and faculty research that has any anesthetic interest, so that this phase of the research may be coincidentally developed and recorded.

The Downtown Anesthesia Clinic

DR. RALPH M. WATERS, Sioux City, Iowa: For a long time there has been a widespread need for some sort of facility for performing minor surgical and dental procedures without taking patients to the hospital. This need has been felt by surgeons and dentists alike, and within the past few years some effort has been made to meet it by the establishing of so-called downtown anesthesia clinics in some of the larger cities of the country by specialists in anesthesia. These clinics are situated, as a rule, in buildings especially arranged for professional service, and within easy access of all means of transportation. These clinics are in charge of some specialist in anesthesia who arranges the apartment to care for patients before, during and after operation, and provides all facilities for the surgeon or dentist to perform any operation that may be desired, under safe and efficient anesthesia, administered by an expert and with proper nursing assistance, if required. In this way the busy surgeon and dentist can accomplish operative procedures without discommoding himself or his own offices, also being relieved of the preparation and after-care of the patients. These clinics have been unusually successful. All professional arrangements with regard to patient and operation are made through the physician or dentist, and all financial arrangements for the service rendered direct with the patient.

Such a clinic must have several retiring rooms fitted for the preparation and after-care of patients, an operating clinic adapted to any minor surgical or dental procedure, with the best of equipment, and a business office. The staff is composed of the anesthetist and an office attendant, and one or more trained nurses as the work done may require.

Anesthesia in the Curriculum and Clinic

DR. WILLIS D. GATCH, Indianapolis: The development of modern surgery has resulted not only in improved methods of administering anesthetics, but also in an intensive study of shock, postoperative complications, and the by-effects of anesthetic agents in relation to the resistance of tissues to disease. Thus instruction in anesthesia must be broadened to include all that is important in this collateral material. To meet this requirement, as a professor of surgery, I emphasize the study of surgical physiology in the second year of the medical course, in which are included all pertinent data regarding anesthesia in its relation to surgical technic and its effects on the patient. Only after the students have been well grounded in these essentials are they inducted into the routine administration of anesthetics. In the clinical work of the third and fourth years the same matters are frequently emphasized at the bedside and in the operating room. By this method we dispense with the necessity of a formal course, and present the subject of anesthesia in its proper relations to clinical medicine and operative surgery.

5 *Migraine in Childhood; Report of Case. W. Tileston, New Haven, Conn.—p. 312.

1. **Calcium Absorption.**—The experiments reported on by Bosworth and Bowditch show that the ingestion of large amounts of calcium and the absorption of this calcium as organic salts, if not accompanied by the ingestion of sufficient chlorin or phosphorus to permit of the formation of soluble salts will result in an accumulation of calcium in the tissues which is followed by a toxic condition and the elimination of calcium lactate in the urine. The toxic condition produced when a high protein synthetic food was fed was probably the result of the high calcium content of the food, and not the result of the high protein content, the protein being responsible only to the extent that it is the carrier of the calcium in the form of calcium caseinate. Whether the toxic condition is the result of the accumulated calcium itself or to a calcium salt, possibly calcium oxalate, the authors are not prepared to state.

2. **Effect of Alkali and Malt Preparations on Retention of Calcium.**—Sato's experiments were made on the same child and with the same malt preparation in order to determine whether the beneficial effect on the calcium retention attributed to malt extracts is due to the extract itself or to the added alkali. He found that the addition of alkali to milk produced not only no favorable effect on the retention of calcium but a distinctly unfavorable one. Malt extract alone without alkali acts beneficially on calcium storage. If malt soup has a favorable effect on calcium metabolism, it is not as a result of the alkali originally contained in it or added to it. Malt extract to which a considerable amount of alkali has been added seems to have a rather unfavorable influence on the calcium balance.

3. **Mercurial Preparations in Treatment of Congenital Syphilis.**—A series of experiments was undertaken by Ramsey and Ziegler to determine, if possible, the extent of absorption of mercury into the circulation as indicated by the elimination in urine, when the ordinary methods and dosage were employed and the time during which mercury continues to be eliminated in the urine after the mercury has been discontinued. The effects of the various forms of mercury on the kidneys as determined by the appearance of protein, casts, or blood in the urine, was also to be estimated when possible. In infants and children, mercury, when given by the mouth, by inunction or intramuscularly, is excreted at least partly by the urine. In new-born infants and older children mercurial ointment when placed in contact with the skin, without any friction being used (protected and sealed by wax paper from being volatilized and inhaled), is taken up by the skin and excreted in the urine and continues to be excreted in the urine for a variable time after all treatment has been discontinued. By inunction (with rubbing) mercury is readily taken up by the skin and eliminated in the urine and continues to be eliminated for a considerable time. When one inunction is given, the maximum daily amount of mercury is usually eliminated during the following twenty-four hours, smaller amounts being eliminated for a variable time. Where continuous inunctions are given there is an accumulation in the system and considerable amounts are eliminated at intervals with only traces between. It is, therefore, probable that it is unnecessary to have mercury in contact with the skin, either with or without rubbing as often or as long as has been generally thought necessary. This, however, must be determined by further clinical investigation.

Mercuric salicylate suspended in oil and given subcutaneously continues to be eliminated in the urine in appreciable amounts for eight days, or longer, the daily amounts eliminated varying widely. It is, therefore, probable that a repetition of the treatment, not oftener than at intervals of eight days would be sufficient. Mercuric chlorid by intramuscular method continues to be eliminated for eight days or longer. In all cases in which mercuric chlorid was used either by mouth or the intramuscular method protein was found in the urine.

Calomel, 0.016 gm. every two hours for four doses, and gray powder, 0.03 gm. every three hours for three doses, continued to be eliminated in appreciable amounts in the urine for as long as nine days; the maximum daily elimination usually occurred during the twenty-four hours following administration. It is, therefore, probable that the daily use of any of the mercurial salts in the amounts usually prescribed, is unnecessary and presumably harmful.

5. **Migraine in Childhood.**—Tileston's patient was 6 years of age. Since the age of 3 years, he had been subject to periodic attacks of headache, accompanied by vomiting. Acetone occurred abundantly in the urine at these times. The attacks came at intervals of from one to three months, as a rule, but had occurred as often as once a week. There was an aura the day before, consisting of pallor, nervousness and an abnormal appetite, usually poor, but sometimes increased to a pathologic degree. The headache was intense and always preceded the vomiting; it was bilateral and frontal in distribution and accompanied by photophobia. The duration of the attack was about twenty-four hours. Between attacks the boy was well and free from headache. There has been a distinct intolerance of eggs; if he takes more than one egg a week he is almost certain to have an attack. He has not taken large quantities of meat. The treatment consisted in withdrawal from school, the correction of the refractive error and alteration of the diet. Throughout the month of Marsh no meat or fish was eaten. During April the child was put back on his former diet. It was now found that he had an increased tolerance for eggs, he has been practically free from headache since beginning of treatment, having had but one slight attack from March to June, 1918.

21. Goitrous Thyroid Following Administration of Thyroid Extract.—When first seen Tracy's patient, a woman, aged 51, was melancholic and sleepy in the daytime. She had a moderate-sized goiter. A half grain dessicated thyroid after each meal was prescribed. After a week's administration of the material the right lobe of her thyroid became painful. The treatment was stopped. After two weeks the painful lobe reddened and a week later "broke," three days after the patient, on her own volition, had applied a bread and water poultice. The mental condition cleared up rapidly after the administration of the desiccated thyroid. Tracy points out that this case illustrates the care with which thyroid extract must be given in such cases. In goiter, with myxedema symptoms, he should commence with half a grain of desiccated thyroid a day, and watch carefully for the least sign of trouble, such as slight pain in the thyroid. On its appearance he omits the medication. Enough may have been given to awaken the dormant tissue to renewed activity. If not, one should carefully renew medication, and watch again.

32. **Studies in Uric Acid Metabolism. I.**—Normal men were maintained by Lewis and Doisy on purin-free high protein diets of high and low content in arginin and histidin. No differences in the excretion of uric acid following the ingestion of these two types of high protein diet were evident. This would indicate that, under the experimental conditions of the present study, arginin and histidin function no more than the other constituents of the protein molecule in the stimulation of the output of endogenous uric acid following ingestion of a high protein diet.

33. **Id. II.**—The subject of this experiment was a healthy young man, 22 years of age, and about 58 kg. in weight. During a period of over six months, a meat-free low protein diet, free also from purin-containing beverages, which may be considered as a purin-free diet, was consumed with the exception of a few meals during the holidays, at which a small amount of meat was taken. No attempt was made to secure a quantitative uniformity of the diet. On the evening preceding the day of an experiment, a light supper was eaten, and no further food was ingested until the completion of the day's experiment, except the substance whose influence on uric acid excretion was to be studied.

Ingestion of purin-free protein food resulted in an increased uric acid output in the fasting subject, which reached its maximum the third and fourth hours after ingestion of the food. No quantitative differences in the action of three types of protein food, cottage cheese, egg white, and gliadin (a wheat protein preparation), in their effect, were observed. Amino-acids also increased uric acid excretion, the maximum effect being produced within two hours after ingestion, more rapidly than in the case of *the proteins*. The effect of the amino-acids is considered to be the result of a stimulation of uric acid production rather than of a more rapid excretion of the uric acid already present in the system, since successive doses of glycocoll on the same experimental day resulted in an *increased elimination* of uric acid in each case. Sarcosin, methyl glycocoll, an amino-acid which does not pass through the same path of catabolism as do the other amino-acids, did not influence uric acid excretion. Ammonium chlorid and urea, products of deaminization of the amino-acids, were also without effect on endogenous uric acid excretion.

Since the secretory activity of the digestive tract is not stimulated by amino-acids, it is believed that the experiments as a whole speak aganst the hypothesis of Mares that the secretory activity of the alimentary glands is mainly responsible for the increased uric acid excretion observed after protein ingestion. It is suggested that the effect is to be considered rather as one due to a general stimulation of all cellular metabolism by amino-acids, the products of the digestion of protein.

36. **Phosphates in Blood.**—On the basis of the results reported by Bloor, phosphoric acid compounds found in human blood may be divided into two classes: (1) the acid soluble—soluble in dilute acids and precipitated with the proteins by alcohol-ether—and (2) the lipoid-phosphoric acid compounds—soluble in alcohol-ether and precipitated with the proteins by dilute acids. The two groups are apparently sharply defined and since, in general, their sum is equal to the total phosphates, the presence of other forms of phosphoric acid combination in blood in significant amounts is doubtful.

42. **Phenols in Blood.**—Phenols have been determined by Theis and Benedict in eighty-three specimens of blood, covering a variety of conditions. Although thirteen different conditions are represented, little difference *in* the phenol value can be detected and that value bears no relation to the amount of uric acid present. Three hernia cases averaged *rather* higher than the others, which perhaps is due to increased intestinal putrefaction. A polycythemia case had been *treated* with benzene for some time, but the phenol was not increased. Ten cases of sarcomas averaged higher than the others.

44. **Antiscorbutic Property of Vegetables.**—To *determine* whether drying at various temperatures, or first cooking and then drying vegetables, destroys the antiscorbutic properties of these foods, Givens and Cohen conducted experiments on guinea-pigs with cabbage and later with potatoes. A small daily addition of raw cabbage to a scurvy-producing diet was found to prevent scurvy in the guinea-pig. Cabbage dried in a blast of air at 40 to 52 C. retained some of its antiscorbutic value in that it would considerably delay the onset of scorbutic symptoms, thereby prolonging life. Furthermore, it could be employed as a dietotherapeutic agent if the signs of scurvy were recognized early enough. Low dried cabbage will prevent scurvy in the guinea-pig and initiate recovery from scorbutic symptoms, provided that the animal will consume a diet supplement of 1 gm. daily. Cabbage heated in an oven for two hours at 75 to 80 C., then dried at 65 to 70 C. for several days lost its antiscorbutic power. Cabbage cooked for thirty minutes, then subjected to drying for two days at 65 to 70 C. exhibited no potency as an antiscorbutic. Potatoes cooked and dried for two days at 65 to 70 C., in the amounts used, possessed no antiscorbutic value. These experiments also indicate that roughage is not the determining factor in the course of scurvy in guinea-pigs. They also confirm the work of Cohen and Mendel in indicating that the antiscorbutic property is not identical with the so-called fat-soluble and water soluble dietary essentials at present recognized.

45. **Colorimetric Estimation of Cholesterol and Coprosterol.** A method is described by Myers and Wardell for the colorimetric estimation of cholesterol in blood, in which the cholesterol is directly extracted from the blood with the solvent (chloroform) employed in the development of the color reaction, thus rendering the estimation very simple. A modification of the method is described whereby it is possible to determine the coprosterol (?) of the feces.

46. **Uric Acid in Blood.**—An experimental study of a number of metallic salts as precipitants for uric acid in a solution alkaline with sodium carbonate was made by Curtman and Lehrman. The results showed that nickel is the best of those tried. A 0.0004 N iodin solution was found suitable for the estimation of small amounts of uric acid provided certain conditions are adhered to. Based on these considerations, a new method has been developed by the authors for the determination of uric acid in blood, the chief features of which are: (*a*) The precipitation of the uric acid by means of nickel aceetate in a solution alkaline with sodium carbonate. (*b*) The estimation of uric acid in the precipitate by means of a dilute solution of iodin. The method was applied with good results to aqueous solutions of uric acid as well as to blood serum to which known amounts of uric acid were added. Low and inconsistent results were obtained when the method was applied to sheep's blood to which known amounts of uric acid were added. This was shown to be due to the inadequacy of the procedure generally employed for the coagulation and preliminary treatment of the blood. The colorimetric method when used in the analysis of samples of the same blood also gave low and inconsistent results for the same reason. Comparison tests show that the volumetric method is fully as accurate as the colorimetric method, and possesses the advantage of requiring no special apparatus.

47. **Nutritive Value of Banana.**—Sugiura and Benedict present a study of the nutritive value of bananas as determined by the maintenance and growth of albino rats when placed on a diet of bananas, or bananas together with certain supplementary substances. It was found that the banana is deficient in (*a*) protein and (*b*) the water-soluble accessory as a foodstuff for the growth or maintenance of albino rats. A diet of bananas, purified casein, and yeast or carrot-extract is sufficient for the perfect growth and reproduction of the albino rat. Such a diet is not, however, adequate for the production of proper milk by the mother. This statement holds true whether the litter of young is large or small in number, showing that the failure in milk is qualitative in nature, and not simply a deficiency in the quantity of milk product. It is interesting to observe that a diet can be adequate for the production of young and for growth after the eyes of the young open, but inadequate for the proper production of milk. Purified casein supplements the banana other than by the simple addition of protein. The casein in the ration cannot be satisfactorily replaced by washed and dialyzed beef.

48. **Antipolyneuritic Substances in Carrots and Yeast.**—Sugiura's experimental results show that the extracts of fresh carrots and crystalline substances from yeast preparation may cure polyneuritis in pigeons in those cases in which the disease has developed quickly; namely, in about twenty days. However, these same substances did not prevent the polyneuritic pigeons from death, if the symptoms appeared more slowly.

49. **Dietary Properties of Potato.**—The results of studies made by the authors show that the dietary properties of the potato closely resemble those of the cereal grains. In this tuber the first limiting factor for growth is the relative shortage of the elements, calcium, sodium and chlorin, as has been found to be the case with the seeds thus far examined. The content of fat-soluble A is too low for the promotion of nutrition at the optimum, and the biologic value of the nitrogen which it yields seems to be of the same order as that of the cereal grains. The results on the value of the potato nitrogen for growth place it in a very different light from those reported by other investigators who have observed its value for the maintenance of nitrogen equilibrium in the adult.

52. **Depression and Rise in Blood Pressure Due to Epinephrin.**—In most dogs, especially mature animals in good health, the intravenous administration of adequate doses of epinephrin (0.5 to 1 c.c. of 1:10,000), after a quick rise in the blood pressure is followed by a rapid fall and a secondary rise. Various hypotheses were investigated by McGuigan and Hyatt. The cause of the secondary rise is apparently due to a central action of the epinephrin acting through the sympathetic ganglions. The basis for this belief is that the removal of the head or pithing of the brain prevents the occurrence of the phenomenon. Also paralysis of the ganglions with nicotin prevents it. It occurs after the sectioning of the vagi and the administration of atropin or pilocarpin. The vagus apparently is not involved in the mechanism. Artificial intracranial pressure during the administration of the epinephrin will cause similar changes in the blood pressure.

55. **Acriflavine in Treatment of Gonorrhea.**—Davis and Harrell made an experimental and a clinical study of various diffusible antiseptics. Acriflavine was found to inhibit the development of the gonococcus in protein-containing mediums in a dilution of 1:300,000. (Has 600 times the strength of protargol.) It will penetrate through the submucosa of the

urethra and bladder. It is nontoxic and only slightly irritating to the urethral mucous membranes. The average duration of a gonorrhea under this treatment is distinctly less than with the usual methods. In an occasional case it seems without effect on the course of the disease. The authors have used dilutions varying from 1:2,000 to 1:1,100, and have found the 1:1,000 most satisfactory; it is just as efficient as the more concentrated solutions and the smarting is less, in fact, with this strength it is almost negligible. There have been no complications following the use of a 1:1,000 solution.

In the anterior cases, about 3 c.c. of a 1:1,000 solution were injected into the anterior urethra the patient retaining it for five minutes. In the posterior cases 15 to 30 c.c. were injected through into the bladder, distending the urethra and having the patient retain the dye in the urethra for five minutes and in the bladder till the next voiding. Injections should be given twice a day until all organisms have disappeared from the discharge and then once a day until the patient is considered well. All results were controlled by daily examination of smears from the urethral discharge and of the urine voided in three glasses. Recurrences were noted as is the rule with any form of treatment. A striking feature of this form of therapy appeared to be that in many cases the dye acts almost as a specific, while in an occasionaal one it seems without any effect whatever.

56. **Urinary Antiseptic Value of Chlormercury Fluorescein.**—This paper is a discussion of the chemistry, antiseptic properties, toxicity and excretion of chlormercury fluorescein, a synthetic compound which, administered intravenously in minute doses, will cause the secretion of antiseptic urine, for a definite period of time, without injury to the animal. Chlormercury fluorescein is formed by the introduction of one atom of mercury into the fluorescein molecule. It is more effective in acid than in alkaline urine, in the case of both the colon bacillus and the staphylococcus. Even in alkaline urine, however, the development of both organisms was inhibited by a diluton of 1:10,000. (Phenol, in urine, permits a growth of the colon bacillus in a concentration of 1:1,000.) It is excreted by the kidney after intravenous injection as rapidly as is phenolsulphonephthalein. Nearly all of the dye is excreted by the normal kidney a short time after injection but this excreton is accompanied by a cleavage in the organism into fluorescein and some form of mercury combination. The lack of toxic effects either immediate or cumulative after large and repeated doses makes it probable that the mercury may find its exit in the feces. No clinical value is yet claimed for this drug.

57. **Urinary Antisepsis with Acriflavine and Proflavine.**—Preliminary experiments made by Davis and White indicate that acriflavine and proflavine may prove of value for internal use in alkaline infections of the urinary tract. Chlormercury fluorescein is relatively more efficient in acid urine.

58. **Antiseptic Properties of Normal Dog Urine.**—According to Davis and Hain normal dog urine, obtained by aseptic catheterization, shows a distinct antiseptic action, which is particularly marked against organisms of the colon typhoid group, less effective against *Staphylococcus aureus,* and entirely inert against at least one strain of *Staphylococcus albus.* This antiseptic action is not constant for all dogs, nor for the same dogs on all occasions. It was exhibited, however, by the urine of one dog in twenty-nine out of thirty catheterizations.

59. **Surgical Treatment of Gonorrheal Epididymitis.**—The operation recommended by Blahd consists simply in making an incision about one-half inch in length through the scrotal wall and tunica vaginalis, immediately over the most swollen area of the epididymis, and permitting the serous or purulent exudate to escape. If the fluid which escapes is serous in character, as is prevalent in the vast majority of cases, the incision is closed with one silkworm gut suture, one or two strands of catgut being left for drainage. The latter is generally removed after twenty-four hours. If pus is present the incision is packed with a small strip of plain gauze and the wound allowed to granulate. Either a local anesthestic or gas is used. It is said that immediate relief is obtained from this simple procedure, and the patent is able to resume his duties in a few days and shortly thereafter to submit to treatment for his urethritis.

3. **Pulmonary Fat Embolism and Traumatic Shock.**—Examination of a considerable number of battle casualties which have terminated fatally at a casualty clearing station has led Sutton to the conclusion that 10 per cent. have pulmonary fat emboli demonstrable by gross methods. He is convinced that this percentage would be increased if sections of lung tissue were stained for fat in all cases. Fat emboli have been found in cases of fractures, wounds involving fatty tissue and wounds penetrating the abdomen, with laceration of the liver. Sutton has particularly noticed that in compound fractures reaching a casualty clearing station with splints imperfectly applied, and where, consequently, immobility was not complete, symptoms, resembling "shock" were invariably present. He has seen pulmonary fat embolism more often following a compound fracture without comminution than with comminution. During a recent crisis, when patients had to be evacuated to casualty clearing stations more hurriedly than in ordinary times a number of cases were received, many in a profound state of "shock." The blood loss in some was not great, as evidenced by the condition of their clothing and stretchers. Among these, few showed any response to resuscitation measures.

In this series Sutton examined the lung tissue in eight cases, and found pulmonary fat embolism in six. Sutton does not claim that all fatal cases of shock are due to pulmonary fat embolism, because the physical and chemical properties of lipemic blood are such that acidosis cannot be avoided, and it is still to be proved whether the terminal mechanism is not the same. The occurrence of pulmonary fat embolism in the war area is much more frequent than has been suspected, owing, probably, to lack of thorough examination of lung tissue for evidence of fat. Associated with pulmonary fat embolism, disseminated fat is found in the other tissues of the body, included in the capillaries. This undoubtedly accounts for the delirium so frequently associated with this condition.

Prophylactic treatment consists in fixation of fractures with extension where possible; early and efficient surgical interference for fractures; at operation on wounds involving fatty tissue it is imperative to secure careful and complete hemostasis, particularly the ligation of the nonbleeding proximal ends of veins as well as the bleeding distal ends. Active treatment is only symptomatic. Small amounts of sodium bicarbonate (2 per cent.) are helpful. The administration should be regulated by the condition of the right heart. Transfusion of blood in small amounts may be useful.

5. **Immediate Treatment of Fractured Femur.**—The principle of the method proposed by Chavasse is the application of very powerful extention, followed by fixation in the extended position. A stretcher and two slings are required. It is the rule for each of the four bearers in a squad of regimental stretcher bearers to carry a sling. Thus two slings are still available for carrying the stretcher (should this method of carying be possible or desirable). If there are no slings, puttees can be used. Spare slings should be available at aid posts.

The procedure is as follows: Expose and dress the wound. Enlarge the adjustable loop of one sling to its maximum by shifting the grip plate as far as it will go. Slip the loop over the foot on the injured side and pass it up as far as the groin. Tie the ankles and knees firmly together (with narrow fold triangular bandages, or other bandages or makeshifts). Open the stretcher and place on it a small pillow where the knees will be. (A waterproof sheet, doubled from side to side and loosely rolled from end to end makes a suitable pillow). Place the patient on the stretcher so that his heels project an inch or two beyond the edge of the canvas, or more if he is a tall man. The heel on the injured side should be a little lower than the other if possible. Adjust the loop of the other sling so that it is equal in length to the distance between the poles of the stretcher (1 foot, 7 inches). Slip it over one handle and wind very tightly about the feet. That is to say, pass it from one handle across the soles of both feet, up across both insteps, behind both ankles, down across both insteps, then through the loop (to avoid torsion of the feet), and thence across the soles of both feet to the opposite pole. Secure by buckling the small strap around the opposite handle, making all as taut as possible. To avoid the small strap tearing away owing to the strain, the small loop to which it is sewn should be turned inside out, thus causing the strap to pass actually through the small loop.

Gently raise the stretcher almost into the perpendicular, so that the patient is hanging by his feet. Draw the patient down head first far as he will come. (If the patient continues to have pain he may be left for a few minutes until the muscles are tired. He may then be drawn down a little farther.) The stretcher may be propped up against something. See that the back of the loop is well behind the buttock. Adjust the loop so that the grip plate will almost lie on the surface of the stretcher when the strain is taken. (This position of the grip plate tends to correct the flexion abduction and external rotation of the upper fragment.) Put a very heavy strain on the groin sling and secure by buckling the small strap around the pole handle by the head in such a way that it does not rotate and slip. While making fast the strong pull must be kept up in order that everything shall be taut after making fast. (There is no possibility of the groin loop constricting the femoral vessels, as in the rifle splint and a badly applied long Liston. For the sling loop is so oblique that it does not cross these vessels at all.) Level the stretcher. Tie a bandage round pelvis and stretcher.

Lay a rifle, bolt removed, along the outside of the limb to steady it. Bandage it in position. The patient is now ready for his journey.

17. **Sensory Changes in Trench Fever.**—Among the patients examined by Jones were about 130 cases of "fever" of various kinds, including trench fever, malaria, cerebrospinal meningitis, scarlet fever, measles, rose measles, mumps, diphtheria and surgical septicemia. Of these, trench fever and malaria were commonly associated with hyperalgesia of three definite groups of segments which do not correspond with those belonging to any viscera. In no other fever was anything of this kind found; cases in which there were clear symptoms or physical signs pointing to inflammation of any viscus often showed hyperalgesia over the appropriate segments, but that was all. The parotitis of mumps, the bronchitis of measles and the nephritis of scarlet fever all showed typical areas, and throughout the fevers, in cases of severity, the eleventh dorsal area, corresponding to the kidney, was often hypersensitive, and when this was so, albumin was nearly always to be found in the urine; this is especially true of surgical septicemia. The inference is that the kidney suffers damage in the process of eliminating bacteria and their toxins. But hyperalgesic areas of unexplained origin were found only in trench fever and malaria.

In these fevers the following were found: the eighth cervical and first dorsal, the seventh dorsal, and the first, second, third, forth and fifth lumbar. This is the full trench fever distribution, and is found frequently in its entirety, and in nearly every case which is diagnosed as trench fever on clinical grounds this distribution is to be found more or less complete.

In this series seventy-three cases of trench fever were examined. The segmental areas of hyperalgesia found were as follows:

Upper Group—		
8 C., 1 D	29	39
1 D. (alone)	10	
Middle Group—		
7 D. (alone)	55	68
7 D. + adjacent areas	13	
Lower Group—		
1, 2, 3, 4, 5, L.	57	67
Incomplete lumbar	10	
"Full Trench Fever"—		
8 C., 1 D.; 7 D.; 1, 2, 3, 4, 5 L.		24
Nil		5

Eighteen cases of malaria were examined, of which sixteen showed precisely similar areas to those found in trench fever. In no other fever was this the case. It is suggested, by Jones that hyperalgesia of these particular segments is diagnostic of a group of diseases consisting of malaria and trench fever, and it is remarkable that one of them is mosquito-borne and the other louse-borne; that both appear to be protozoal, with a definite cycle of development, as shown by the periodicity of the febrile attacks induced by them; that both appear to lie dormant for considerable periods within the body; and that both are associated with enlargement of the spleen. These hyperalgesiae are precisely similar to those found in inflammation of the viscera, but it is difficult to see to what viscera they can correspond, though a few possibilities suggest themselves. The eighth cervical and first dorsal areas, perhaps, indicate an affection of the thyroid; a case of acute thyroiditis examined showed some hyperalgesia of the first dorsal. The seventh dorsal area may possibly indicate the spleen, which is enlarged in both the diseases concerned, or else the suprarenal gland, since there is evidence of increased excitability of the sympathetic in trench fever. Also the physiologic association between thyroid and suprarenal should be borne in mind.

The cause of hyperalgesia of the lumbar segments is quite obscure; it does not appear to be any condition of the small intestine, kidney, testis or large intestine, and it is difficult to see what remains. In the only two cases of cystitis examined some lumbar segments were found involved, in one of them the first three, but the absence of symptoms pointing to any vesical disturbance makes such a view difficult to accept; at present it must be said that the significance of a lumbar hyperalgesia in these diseases is unexplained.

24. **Transfusion of Blood in War Surgery.**—The indications for transfusion of blood in war surgery according to Harrison are: (1) anemia, caused by (*a*) loss of blood, (*b*) prolonged sepsis; (2) retarded healing of wounds, including compound fractures. In primary hemorrhage, with suitable conditions and suitable blood, it is always beneficial. In secondary hemorrhage and sepsis transfusion causes increase in volume and constituents of the blood; increase of coagulability of blood, which often stops the capillary oozing so frequently found in septic cases; increased healing, appetite, and well being of patient; lowering of pulse rate and temperature; loss of edema and albuminuria. If the transfusion is not carried out with "technique de rigueur," and an efficient agglutination test has not been carried out, certain alarming or even fatal results may take place. Immediate: hemolysis, agglutination, possibly causing sudden death; cyanosis, with feeble pulse, possibly caused by giving too large a volume of blood when the heart muscle is degenerated from sepsis. Later: sweating, rigors, pyrexia, apparently found more frequently after giving citrated blood; hematuria.

32. **Iodids in Syphilis and Yaws.**—In the past three and a half years Spittel has given over 5,000 injections of a modification of Donovan's solution in syphilis and yaws. In an emergency, a very efficient injection may be made out of ordinary Donovan's solution, diluted with an equal quantity of strained sterile water; it is then rendered slightly alkaline by adding drops of a 15 per cent. solution of sodium hydroxid while testing with litmus paper. The dose of this is from 7 to 12 c.c. for intravenous administration. Its disadvantage

is that it contains too much mercuric iodid, and is apt to cause much salivation if not cautiously used. The solution Spittel uses as a routine is as follows: mercuric iodid, 50 grains (3.24 gm.); arsenious iodid, 40 grains (2.59 gm.); sodium (or potassium) iodid, 8 drams (28.42 c.c.); distilled water, 40 ounces (1,000 c.c.). The dose for an adult is 8 to 15 c.c., small to begin with and gradually increased according to tolerance. Four to six injections at intervals of four days to a week constitute a course. Several such courses should be given, with intervals of a month or six weeks between them.

The injection is administered with a 20 or 30 c.c. glass syringe, into which the required quantity of solution is drawn; the syringe is then filled up to its full capacity with sterile water. This further dilution is necessary to obviate the slight phlebitis that is otherwise apt to ensue rendering future injections into the same vein somewhat difficult. The solution is introduced into the vein after the usual manner of intravenous injections; should any of it escape into the tissues outside the vein, pain, tenderness and induration are caused. The reaction depends on the dosage employed; it is negligible and evanescent if the dose is graded to tolerance. Heart and kidney disease are no contraindication to cautious dosage.

One or more of the following symptoms may be produced within a few hours of injection: chill, fever, malaise, headache, vomiting, pains and a burning sensation in the body. Later effects are gingivitis and salivation, coryza, lacrimation, diarrhea and griping.

33. **Technic of Large Intravenous Injections.**—Whiteford injects the solution into the vein by means of a Higginson enema syringe. The apparatus required includes a Higginson syringe, to which is attached 1 foot of stout walled rubber tubing, with a lumen of one-eighth inch. At the end of this tubing is a metal cannula with a bulbous point. All injunctions are secured with stout silk, tightly tied. The solution is contained in an enamelled iron jug, the mouth of which is 5 to 6 inches in diameter. A piece of tape, or stout silk, is attached to the syringe, just beyond the bulb, and its ends tied to the handle of the jug, in order to prevent the syringe from slipping out of the jug. The vein is exposed, the syringe, tubing, and cannula are filled with solution by a few squeezes of the bulb and the cannula is tied into the vein. The force required to make the solution pass through the lumen of the actively contracted vein of a shocked patient is considerable and is worthy of notice by those who contend that in shock the veins are in a state of dilatation. As soon as the cannula has been tied into the vein only one pair of hands is required to attend to the injection.

37 Streptococcus Responsible for Complications of Influenza. Le Marc'hadour and Denier.—p. 233.
38 Influenza. Antoine and Orticoni.—p. 235.

36. **Cardiovascular Disturbances in Aviators.**—Berthier found the liver extremely congested in one aviator and also, accompanied by organic lesions, in a second. Both the young men had been taken with vertigo and had lost consciousness on reaching a high altitude. The heart seemed sound on superficial examination, but the blood pressure was very low and, in the morning, in bed, the pulse was weak and slow. He urges the necessity for systematic testing of the blood pressure of aviators with the Pachon oscillometer, as this records the minimal pressure. Any tendency to liver disturbance and nervous upset is liable to affect the circulation dangerously, when the blood pressure is too low. He is convinced that the aviator himself, and not the stalling of his engine, is often responsible for the fatal accidents.

49 *Early Diagnosis of Tuberculosis. Sakorrafos.—p. 661.
50 Syphilitic Hyperostosis. Sakorrafos.—p. 662.

39. **Incontinence of the Pylorus.**—Hayem refers to an article recently summarized in The Journal, abstract 34, page 1011, saying that what the writers call incontinence of the pylorus is the same disturbance which he described eleven years ago as premature evacuation of the stomach. He said then that the resulting diarrhea is the triumph of kefir treatment. It may benefit likewise when there is constipation instead of diarrhea. Bismuth subnitrate may sometimes prove useful in the same way.

40. **Acute Mikulicz' Disease.**—The parotitis had a sudden onset simulating mumps, but it passed into a chronic phase, and the lacrimal glands shared in the process. The Wassermann reaction is strongly positive.

41. **Progressive Muscular Dystrophy.**—In the case described there was no apparent disturbance in carbohydrate metabolism, no creatin in the urine, and nothing to indicate an endocrine origin. The thyroid and the pituitary body seem to be normal.

42. **Acute Nephritis with Gangrene.**—Seven years after pneumonia with albuminuria of 7 gm. to the liter, acute nephritis developed in the man of 34, with gangrene of the right leg. Several similar cases are on record; in some the gangrene affected all the extremities. The patients were all comparatively young and they speedily succumbed. The gangrene in the majority was of the dry type.

43. **Emetin in Bilharziasis.**—The emetin was injected by the vein, a total of 0.92 gm. in thirteen injections in five weeks. No ova were discovered after the eleventh injection, and there was no further hematuria or pain after the completion of the course during the month the young man was under medical supervision.

45. **Fate of Bone Graft in Skull.**—Sicard is an advocate of utilizing a piece of bone from another skull to close a gap in the skull. The graft is cleared of fat, and is sterilized, and fitted into the breach where it is fastened with catgut. Necropsy ten months after one operation of the kind showed the complete tolerance of the tissues, and that the catgut had sufficed to fasten it securely in place. Each surface of the bone graft had become covered with a dense and extremely resistant fibrous membrane, solidly adherent to the adjoining tissues. Only the inner surface of the bone graft showed slight signs of a tendency to resorption.

48. **Albumin and Blood in the Stools.**—Labbé and Canat found soluble albumin in the stools in about 16 per cent. of 113 cases of chronic gastro-intestinal disease, and acetoprecipitable albumin in about 50 per cent. Blood was found in 5 per cent. Comparison of the findings with the clinical course shows that the presence of acetoprecipitable albumin in the stools is a sign of moderately severe dyspepsia; soluble albumin, of grave dyspepsia. The presence of blood in the stools is also a sign of grave gastro-intestinal disturbance, but not necessarily the same kind of disturbance as in the cases with soluble albumin, although they are frequently associated. The blood comes from some bleeding point in the digestive mucosa, but soluble albumin, they reiterate, points to ulceration.

49. **Early Diagnosis of Tuberculosis.**—Sakorrafos warns that completely healed lesions in the chest, of tuberculous or other origin, may give roentgen findings liable to be mistaken for florid tuberculous lesions. On the other hand, he thinks that tuberculosis may be regarded as certain, although there may be no signs of pulmonary involvement, when the glands in the neck, axilla and inguinal region are hypertrophied and the blood shows pronounced lymphocytosis. It may also be regarded as certain in tall, blonde young men with tachycardia and low blood pressure, high urea and high phosphate content of the urine, the chest long and narrow, with poor expansion, and often a tendency to pityriasis versicolor. Under the influence of the physical stress of active service and unhygienic living, men in this group develop pulmonary tuberculosis. Sakorrafos is professor of clinical medicine at Athens.

56 *Lip Reading.* H. *Marichelle.*—p. *145.*
57 Locomotor Sequels of War Wounds. A. Mouchet.—p. 145.

53. **Fractures of the Forearm.**—Destot says that surgeons are constantly sinning against four great laws that should govern every case of fracture of the forearm, namely, that the relative length of the two bones must be maintained, as also the natural curve of the radius and its excentric position, and the hand must be kept in supination to maintain the bones in the normal axis. An immediate prosthesis is necessary to guide cicatrization and prepare conditions for a secondary graft. He reiterates that if surgeons could follow their cases of fracture of the forearm to final healing, they would appreciate better the difficulties of correcting parts healed in a vicious attitude, and they would realize what might have been done to avoid this. Especially in the matter of grafts improved technic is desirable. He describes a useful instrument for cutting grafts, etc.

55. **Liver Tissue in Local Treatment of Wounds.**—Savini recalls the statements of Schoull and Weiller that wounds healed more rapidly when treated with lipoids from the liver. This treatment was suggested, he says, by the current observation that the spontaneous appearance of jaundice in the wounded shortens considerably the healing of the wounds. Vigen in 1915 reported excellent effects on the healing of burns and torpid wounds of an ointment composed of lard, wax, olive oil and beef gall. Savini then applied the principle, using an ether extract of chopped liver tissue, desiccated at 70 C., pulverized and placed in a Soxhlet apparatus to extract the lipoids with ether. The lipoids thus derived are emulsified at 5 or 10 per cent. in olive oil. To keep it aseptic a little ether is added from time to time. Before using, it is warmed by setting it in hot water, and is well shaken. He sprinkles the wound with this about every second day, after lavage with saline, and applies a dressing. The results have been very encouraging; he reports some typical cases. He has found it particularly useful in promoting the healing of Thiersch flaps, and of varicose ulcers and suppurating hemorrhoids, of burns from flame and from caustics, and also for lavage of the intestines in local treatment of colitis, and in ulceration of the uterine cervix. No effect was apparent with eczema or syphilitic lesions. The lipoids probably act as general stimulants of the cell functions, activating their defensive power and their capacity for regeneration in a remarkable manner.

Presse Médicale, Paris

Sept. 23, 1918, **26**, No. 53

58 *Treatment of Acute Arthritis. P. Nolf.—p. 485.
59 *Lethargic Encephalitis. P. Sainton.—p. 487.
60 *Secondary Suture. Ehrenpreis.—p. 490.
61 *Quinin and Malaria. G. Pépin.—p. 492.
62 Factitious Skin and Venereal Lesions. R. Burnier.—p. 493.

58. **Treatment of Acute Arthritis.**—Nolf has published several reports on the efficacy of parenteral injections of peptone in treatment of infectious diseases, alone or with other therapeutic measures. He here gives the details of a few cases which seem to show the superior efficacy of association of peptone with the usual sodium salicylate treatment in rebellious cases of acute articular rheumatism, and also in septicemia from the staphylococcus or hemolytic streptococci. He uses 8 or 10 c.c. of a 10 per cent. solution of peptone, with or without 0.5 mg. epinephrin. If there is reason to anticipate much of a reaction, he dilutes it in 150 or 200 c.c. of isotonic saline solution. The intravenous injection is made very slowly, under constant control of the pulse, suspending the injection if the pulse runs up above 35 per quarter minute, and waiting a few moments until the pulse calms down.

59. **Lethargic Encephalitis.**—Sainton analyzes what is known to date in regard to lethargic encephalitis. He is inclined to regard it as the result of the localization in the brain of the prevailing influenza. This is suggested among other things by the coincidence of the two epidemics, both this year and in 1890, by the purulent rhinopharyngitis of both diseases, the similar onset, and the long period of weakness afterward. Lethargic encephalitis has less analogy with poliomyelitis, especially the difference in the age of the patients, the absence of a meningeal reaction, the lesser changes in the nerve cells, and finally the complete, integral recovery.

60. **Indications and Technic for Secondary Reunion of Wounds.**—Ehrenpreis gives six illustrations to demonstrate the preferable technic. The wound must be clinically sterile, flat, and the sutures must be applied without tension, each tier of soft parts sutured separately.

61. **Best Technic for Quinin Administration.**—Pépin urges the importance of watching over the elimination of quinin as a gage for its absorption and therapeutic efficacy, and a guide for the next dose. Twenty-two persons, sick and well, were given an intramuscular injection of 0.8 gm. quinin and the proportion eliminated in the urine was determined at regular intervals. One healthy person eliminated 21 mg. in the second hour urine; 46 mg. the twentieth hour, to a total of 216 mg. in forty-eight hours. Corresponding figures in a malarial subject were 13 and 54 mg. to a total of 158.6 mg. in forty-eight hours and 161.4 mg. in sixty-nine hours. In one case, 0.8 mg. were refound in the urine in thirty minutes. The quinin could also be recovered from the stools. He gives findings also after the quinin had been administered by other technic. He does not give his technic for extraction of the quinin, as it has been already published in the *Bulletin des sciences pharmacologiques,* January-February, 1918, **25**, 19.

70 *Local Treatment of Anorectal Lesions. A. Bernard.—p. 300.

64. **Shock.**—Cannon is professor of physiology at Harvard, and this article is a summary of an address made at a meeting of the Société médicale franco-américaine at Dijon. Among the points he emphasizes is the necessity for warming up from the very first a man in shock. If hot water bottles are used, one should be placed at the feet and one on the abdomen, covered by the hands, one in each axilla, and one between the thighs. No operation should be attempted until the blood pressure has been raised above the critical level; this seems to be 70 mm., or 80 mm. in case of hemorrhage.

65. **Italian Method of Grafting.**—Bonneau describes the technical points for applying this method to grafting operations on the legs.

67. **Intravenous Injections of Hexamethylenamin.**—A review of practically the same article was published, Oct. 19, 1918, p. 1350.

68. **Pathogenesis of Meningitis.**—Lochelongue says that in his work as chief of a bacteriologic laboratory he has been

impressed by the way in which the presence of sugar and of albumin promotes proliferation of bacteria in culture mediums, and also in the cerebrospinal fluid. Hence he suggests that before any operation on the skull and in general infections the spinal fluid should be tested for sugar. An overhigh sugar content should be regarded as calling for special prophylactic measures. He adds that addition of a little sugar to specimens of fluid being sent in for examination will be more apt to maintain the vitality of the meningococci.

70. **Medication of Anorectal Lesions.**—The *introducteur* is a blunt tube with holes in the side near the tip. The salve placed in it is forced out with a piston. A rubber ring is adjusted on the tube to ensure that it enters the rectum only to the exact depth required. The patient can then continue the treatment himself.

71. **Cooperating Factors in Tuberculosis.**—Breccia reiterates that the campaign against tuberculosis requires centralization as a government function.

72. **Traction on Soft Parts of Stump.**—When the skin flaps had to be cut too short to cover the stump, Fiori has succeeded in pulling them down by traction with weights hung from a loop formed by two strips of adhesive plaster crossed over the stumps and carried high up on the skin. By shifting the traction to different points of the plaster loop, the skin can be drawn down evenly all around. Healing was complete in thirty-five days in a case described in which the soft parts had been extensively sacrificed on account of gas gangrene.

73. **Influenza.**—Pontano discusses the epidemic from the clinical and other points of view, remarking that not a corner of the country (Italy) seems to have escaped. When several members of a household are attacked, the passage of the germs through others seems to enhance their virulence. The epidemic begins to decline in three or four weeks, and after six weeks no new cases develop. All ages are affected, but the smallest proportion of cases are among the elderly, and the disease is milder in them, suggesting eventual immunization from preceding epidemics. The general mortality from the epidemic has been 2 or 3 per cent. The incubation period does not seem to be more than one or two days. In Pavesi's experience, the epidemic spread by zones, like a cyclone, but he could always trace possible carriers.

74. **The Bipolar Bacillus of Influenzal Septicemia.**—Ciauri is director of the Stazione sanitaria marittima at Cotrone. He here reports the cultivation from the sputum and blood of patients with severe influenza of a micro-organism which induces septicemia in guinea-pigs. It appears in two forms, rods and ovals, but both take the stain strongly at both poles. The rods are gram-positive, the ovals gram-negative, but the two are always found together in the cultures. This bacillus was found only in the graver cases, those which seemed to be of a septicemic type. He calls it the bipolar diplomorphous hemoseptic bacillus. It does not develop on Endo-agar nor in Haffkine bouillon, and in glucosed agar it loses its bipolar staining properties, and there is no gas production. On plain agar plates, small low colonies develop in twenty-four hours, the outline slightly wavy, with the central portion granulated like yellowish sand. On Drigalski agar it forms small, polycyclic colonies with uneven surface, like a map in relief. [A cable news dispatch gives further details, such as that rats, fowls and rabbits are not susceptible to infection with this bacillus, and that up to five days may be required for the colonies to develop in culture mediums.]

75. **Urea Test of Kidney Functioning.**—Pirondini's work in this line has been previously described (Aug. 28, 1915, p. 835). Time seems to have confirmed the value of this test. The patient reclines, and the urine of a half hour is collected. Then he drinks 150 or 300 c.c. of water in which 10 gm. of urea has been dissolved, and after this the urine is collected at half hour intervals, the volume, urea content per thousand and the absolute content being recorded for each specimen. In all his cases the findings strictly paralleled the Ambard ureosecretory constant and the results of the phenolsulphonephthalein test. In four of six cases of infiltrating bladder tumors, the urea test findings corresponded perfectly to the necropsy findings in the kidneys. In two of these fatal uremic cases the liver was found extremely pathologic also. Catheterization of the ureters is not usually necessary. The functional disturbances which this induces are liable to obscure the interpretation of the findings. He extols various advantages of this test over experimental polyuria and other tests, and relates the findings with it after nephrectomy, especially in the pregnant. He reiterates that nephrectomized women may bear healthy children, even when the nephrectomy had been done with a pregnancy already under way.

76. **Gas Infection of War Wounds.**—Calo emphasizes that venous stasis offers specially favorable conditions for development of gas infection, and cites cases in which this or tetanus occurred without a wound, the limb being merely frostbitten. Wounds of blood vessels and "closed" wounds are the ones in which gas gangrene develops by preference. When the conditions suggest that it is impending, besides ample opening up of the wound to let the air penetrate into its remotest crevices, preceded by scarification of the venous territory in the infected zone, he urges generous venesection followed by mummification of the tissues affected with the gas infection. The tissue can be "mummified" with the actual cautery, a hot iron, or with unslaked lime. The lime absorbs powerfully the secretions and draws the water out of the tissues, reducing it to a mummified condition not only on the surface but down through the entire mass of the infected tissues, while it has no action on the sound tissue. It thus mummifies selectively; searing with a hot iron, etc., destroys the sound along with the infected tissues. The latter are evidently softened and the cells separated by the action of the anaerobes, so the calcium can penetrate the tissue, while it is unable to permeate normally compact tisssues. The calcium disinfects also as it works into the tissues. He has never had any mishaps with it, not even disagreeable sensations in wounds, etc., treated with it. The best quality of anhydrous lime on the market is powdered fine and kept in sealed packages till ready to use. It is scattered freely over the raw surfaces after the surgical toilet, trying to get it into every recess of the wound. When the gas infection is spreading, amputation must be prompt and quick—plane amputation close to the root of the limb, with live lime to the stump.

77. **Cure of Tuberculous Goiter.**—Giacinto reports the case of a nun, 42 years old, who for eight months had noticed that the right lobe of the thyroid gland was enlarging. Irregular neuralgic pains were also felt in the tumor, irradiating downward and outward or upward. These pains were variable, appearing usually in the evening, and were not modified by the ordinary sedatives. The temperature rose slightly toward evening. The hard tumor was tender, with irregular surface, and immovable except for slight movement during swallowing. There was slight emotional tachycardia, but no signs of exophthalmic goiter. The urine was normal. The weight had dropped over 15 pounds in two months. The diagnosis wavered between malignant goiter and woody thyroiditis, but an exploratory incision showed the capsule much thickened and bound down to adjacent tissues. A wedge was excised, 5 cm. long by 3 cm. wide; the inner end seemed to be normal tissue, but a cheesy tubercle was apparent above. No tubercle bacilli could be discovered. Treatment was by daily injection of alternating iodin and arsenic. Then two

weeks after the exploratory operation, when the wound was covered with granulations, the thyroid was exposed to the roentgen rays. Six exposures were made of ten minutes each in the course of six weeks. By the fourth exposure the pains were less, and the thyroid began to subside. Each exposure was followed by malaise and general prostration which was thrown off in twenty-four hours. In two months the wound was almost completely healed but the evening rise in temperature persisted a while longer. By the fifth month the patient had gained 22 pounds in weight, the complexion was good, there had been no pains for two months and the thyroid had returned to normal size and consistency except for slight hardness of the upper pole of the right lobe. The clinical recovery has persisted unmodified to date. No trace of tuberculosis elsewhere had been found at any time except a few small hard, movable and indolent glands in the right supraclavicular region, which were apparently not influenced by the treatment. Giacinto has found nine operative cases of tuberculous strumitis on record with an abscess; two terminated fatally and in one a fistula persisted. In the nine cases of ligneous tuberculous thyroiditis, three of the patients succumbed soon to complications, or to thyreopriva cachexia. The operation was done in these nine cases on assumption of cancer. The roentgen rays demonstrated a curative action also on an extensive tuberculous lesion on the tongue in a case reported by Stropeni in 1913. Gebele has published a case in which, after resection of part of the thyroid, the remainder was treated by roentgen exposures, and permanent clinical recovery followed. The retrospective diagnosis was tuberculosis.

78. **Tests of Kidney Functioning in the Young.**—Pirondini reports application of the urea test (described in Abstract 75), to children over 6 to puberty and to adolescents. The findings seem to indicate that the smaller size of the kidneys in the young is compensated for by a higher functional capacity, so that the functional performance does not differ materially from that in adults.

82. **The Anatomist of the Labyrinth.**—Gradenigo quotes from the great Italian work of D. Cotugno, 1761, to show that the latter was the pioneer in the anatomy and physiology of the internal ear. Time has confirmed the correctness of his statements, but Helmholtz published the same thing in 1862 as the results of his own original research, with no reference to Cotugno. Gradenigo suggests that it might be to the advantage of other nations, as well as Italy, to begin to take an inventory of their scientific patrimony, instead of continuing to accept at its face value the frequently recurring "Made in Germany" stamp.

89 *Normal Horse Serum in Treatment of Anthrax. A. B. Langon.—p. 258.
90 Negative Seroreactions in Typhoid. A. N. Berta.—p. 265.

85. **Gastro-Intestinal Derangement in Young Infants.**—In this concluding instalment of his long study of this subject, Morquio discusses the therapeutic indications after the diet has been regulated. He discusses further the treatment of malnutrition and of diarrhea from other causes than the food. He emphasizes in particular that calomel is directly contraindicated in this latter type of diarrhea, and he does not advise its use for digestive disturbances of any kind in infants. In fact he declares that purges are given too much in treatment of infants. In some exceptional cases diarrhea may develop at some phase of teething, appear and disappear with it, without any other cause being apparent. If the gum is much swollen and the tooth close to the surface, the diarrhea may justify lancing the gum although he does not advise this as a regular thing. He warns that the urine should be examined for evidences of nephritis whenever we encounter a clinical picture in an infant which we are unable to explain. Palpation of the kidney may reveal a swollen pelvis. This is particularly liable to be encountered with digestive or influenzal infectious processes, or both combined.

86. **Occupational Diseases.**—Rossi discusses the pathology of labor as the first lecture of a course on occupational diseases.

87. **Cancer of Uterine Cervix in Pregnant Woman.**—Bottaro and de Bengoa report the cure of the cancer under radium and the successful termination of the pregnancy—the case apparently demonstrating that the fetus does not suffer from radium exposures, at least after the fifth month. The woman was at about the seventh month of her sixteenth pregnancy (with thirteen living children), and an infiltrating carcinoma, starting in the cervical mucosa, had been probably responsible for occasional metrorrhagia during the last twelve months. There had never been any pains. Six radium exposures were given in the course of six weeks, under which the neoplasm decidedly retrogressed. Then a vigorous child was extracted by cesarean section, which was followed by panhysterectomy. Six weeks later the radium exposures were renewed and supplemented with roentgen exposures. The woman has seemed to be in good health during the months since. The cicatrix in the vagina is movable, and there is no pain on pressure anywhere.

In conclusion they call this the "rochar" method of treating cancer of the cervix during pregnancy. This term is made up from the initials of the procedures applied, namely, radium, observation, cesarean, hysterectomy, annexectomy and radiations. They add that V. Asa of Madrid has reported a similar case, confirming that the radium exposures do not damage the fetus. Aza's patient, however, succumbed to heart disease in less than three weeks, so their case is the first conclusively successful one of the kind.

89. **Normal Horse Serum in Treatment of Anthrax.**—Langon reports 13 new cases, which added to Montebruno's 4 and 18 he has previously published, bring to 35 the number of patients with anthrax given subcutaneous injections of normal horse serum. He began with 30 or 40 c.c., to a total of from 40 to 100 c.c. and the lesion healed over promptly in every case, with no signs of serum sickness. Some of the cases were extremely severe ones but there was no mortality.

98 *Case of Beriberi in Spain. J. G. Castro.—p. 690.

94. Bladder Stones.—Martin calls the concretions which develop in an inflamed organ secondary calculi, and reports ten cases of the kind in children and in adults. The stones perpetuate the inflammation. Some of his cases emphasize the necessity for refraining from the use of silk in operations on the urinary passages, as it is liable to form the nucleus for stones. Also the necessity for keeping up the clearing out and disinfecting of the bladder until the interior surface has entirely healed over. Otherwise salts may be deposited on some scrap of tissue sloughed off around the high incision.

95. Congestive Form of Hypothyroidism.—Summarized on page 321 of The Journal, July 27, 1918, when it appeared elsewhere.

96. The Dynamics of the Heart.—Garcia discusses the effects on the heart activity of stimulation of the vagus nerve under different conditions of repletion and isomeric contraction.

104 Paretic Dementia; Negative Wassermann Reaction. H. Bolten.—p. 85.

99. Treatment of Asthma and Rhinitis.—De Kleyn and van Leeuwen confirm the statements of others in regard to the changes in uric acid metabolism just before, during and after an attack of asthma and attacks of vasomotor rhinitis. They tabulate the metabolic findings in twelve cases on a purin free diet, and during and after a day on which 100 gm. each of meat and of kidney or sweetbreads had been ingested. In comparison with normal persons, the excretion of uric acid in the urine was of the same type as in gout. This suggested treatment on the same basis as for gout, reduction of the purins in the diet and antigout drugs. The effect was remarkable in some of the rhinitis cases, and some benefit was apparent in the asthma cases but less pronounced. The significance of the abnormal conditions in respect to elimination of uric acid in their cases of asthma and vasomotor rhinitis was enhanced by the frequent discovery of metabolic diseases in other members of the families, especially gout. They urge others to inform them of cases of vasomotor rhinitis, asthma, gout and hay-fever in one family, specifying whether the diagnosis of gout is based on metabolic research or on the gouty big toe. The outlook is encouraging for great relief and improvement in vasomotor rhinitis under abstention from purins, with calcium chlorid according to indications, and possibly other antigout drugs. Acid drinks and dishes should be avoided as well as the purins.

100. The Blood Picture in Pneumonia.—Benstz examined the blood every noon before the midday meal in forty-four cases of croupous pneumonia. The displacement to the left of the Arneth count was most pronounced in the severer cases. Examination of the blood therefore usefully supplements and confirms the findings of clinical examination.

105 *Functions of the Cerebellum. S. Ingvar.—p. 1137.

105. Functions and Topography of the Cerebellum.—Ingvar presents an array of arguments, based on original research and the findings of others, to sustain the assumption that the main function of the cerebellum is to maintain and regulate the static and kinetic forces of the body, combating by reflex action the attraction of gravity and inertia. The remarkable uniformity in the structure of the cerebellum through the entire series of vertebrates is thus not so wonderful as it seems without this explanation.

110 *Roentgen Treatment of Exophthalmic Goiter. S. Nordentoft.—p. 1371. Commenced in No. 34, p. 1331.

110. Roentgen Treatment of Exophthalmic Goiter.—Nordentoft reports fifty cases of exophthalmic goiter given roentgen treatment, and discusses the participation of the thymus. The roentgen exposure was made for from forty to sixty minutes, at one sitting. Two or three exposures generally sufficed, with intervals of from four to eight or six weeks. The subjective improvement was marked from the first, the restlessness, tremor and subjective heart disturbances subsiding first, the goiter and exophthalmos more gradually; the tachycardia last of all. Even in the most favorable cases, the patients still display an unstable pulse and tendency to tachycardia on slight provocation. In several cases the desired effect was realized with a single exposure. This method of a few large doses with long intervals may be better adapted for certain cases than for others, as time will reveal. In any event, it is far more convenient for all concerned than a larger number of smaller doses. His fifty patients were given a total of ninety-nine sittings; in eighty-four the thymus was exposed as well as the thyroid, as he is convinced that the thymus is a factor in certain cases of exophthalmic goiter. He cites a number of cases from the literature in which with exophthalmos and tremor, etc., the thyroid was of normal size while the thymus was much enlarged, and marked improvement followed thymectomy. The thyroid and the thymus under other conditions seem to have an antagonistic action, but with exophthalmic goiter they seem to work in concert.

He presents series of data which sustain the assumption of a "thymus Basedow" and a "thymogenous exophthalmic goiter." If the thymus is mainly responsible, then removal of the thyroid would have little effect on the disease. The thymus is the organ that should be removed in such a case. This might entail spontaneous retrogression of the thyroid. These assumptions throw light on the 20 per cent. of failures reported in the larger statistics of thyroidectomies. He describes several cases of probable thymus origin, one in a man of 50 who had been under treatment for exophthalmic goiter two years before. The tachycardia, palpitations, slight exophthalmos, tremor, and Graefe's symptom, but no Moebius' symptom, were not accompanied by goiter, but they were so severe as to incapacitate him completely. His thyroid and thymus were given a single roentgen exposure, and within two months apparently complete health was regained and has persisted during the five months since.

Such experiences teach the necessity for applying roentgen treatment to the thymus as well as to the thyroid, or possibly to the thymus alone at the first sitting. Operative removal of the thyroid should not be done until after the failure of roentgen treatment, which Nordentoft says will be of rare occurrence. He queries whether it is not our duty to expose the thymus to the roentgen rays before any operation on the thyroid. In Søling's postmortem examination of eighteen exophthalmic goiter cases he found a persisting thymus in sixteen. The question also arises whether the cases of exophthalmic goiter that respond most promptly and favorably to roentgen treatment may not be those of thymogenous origin. Thymectomy is a dangerous operation, but the thymus is exceptionally sensitive to the roentgen rays. The effect begins to be apparent in about twenty-four hours. He reports some cases of spasm of the glottis with hypertrophied thymus, cured by roentgen exposure of the thymus. In conclusion he cites statistics showing 13 per cent. fatal cases of exophthalmic goiter among 1,300 given medical treatment alone, and 25 per cent. in the seventy-five cases at the Frederiks Hospital. In contrast to this is the zero mortality in Fischer's ninety-four and his own fifty cases given roentgen treatment. The full details of his fifty cases are tabulated. More or less benefit was realized in all and the improvement has persisted to date; only a few have been lost track of.

Vol. 71, No. 21 CHICAGO, ILLINOIS November 23, 1918

MULTIPLE INFECTIONS

A STUDY OF THE RELATION OF ONE INFECTION TO ANOTHER *

WILLIAM W. DUKE, M.D. (Kansas City, Mo.)
Physician Attached to the American Red Cross
FRANCE

It is generally recognized that when a person has one or more infectious diseases, one may influence the other occasionally to the apparent advantage of the patient; but more frequently to his disadvantage. In other words, increased susceptibility to one organism may result from infection with another. This subject has been dealt with in the literature under such titles as mixed infection, metastatic infection, secondary infection and focal infection. It may be illustrated by familiar clinical examples. It is well known, for instance, that latent tuberculosis may become active and rapidly progressive after an attack of tonsillitis, measles or pneumonia. Osler mentions the fact that quiescent maladies, such as congenital syphilis and tuberculosis, may be lighted into activity by vaccination. Urethritis or chronic prostatitis is often unfavorably influenced by the onset of a new infection. Urethritis that is apparently cured may occasionally recur after an attack of tonsillitis, bronchitis or other acute infection. In a patient whom I observed, a urethral discharge in which gonococci were abundant was noticed a few days after a severe attack of tonsillitis. The patient gave a history of having had urethritis two years previously, but since that time had apparently been well and had not been exposed to fresh infection. Chronic cystitis of a mild type may become severe following an attack of diarrhea, cholecystitis or appendicitis. A patient who had specific disease that had been thoroughly treated and had been apparently latent for four years was covered with a copper colored papillary rash and gave a positive Wassermann test at the end of the first week of convalescence from typhoid fever. Another patient had an attack of pneumonia after the appearance of an acute alveolar abscess. Several weeks later he had a recurrence of active tuberculosis that had been latent for many years and had not interfered with the most active mental and physical work.

Chronic infections of a milder nature may also have a deleterious influence on other infectious diseases with which a person may be afflicted. This influence is often quite marked. The ill effect of chronic infections of the nose and throat on persons with tuberculosis is generally recognized, and proper local measures for the cure of these are looked on as an important part in the regimen for treating tuberculosis in many institutions. Oral sepsis may have an important influence on tuberculosis, and the eradication of oral sepsis may be of material value in arresting the progress of the disease.

Staphylococcic infections of the skin, such as acne and chronic furunculosis, according to Sutton, are often more amenable to treatment after the eradication of infected tonsils, alveolar abscesses, etc. In a patient with *Staphylococcus aureus* septicemia of more than two months' duration, the temperature fell to normal a few hours after the extraction of an infected tooth and remained normal for ten days. The case eventually ended in complete recovery. The roots of the tooth showed *Streptococcus viridans* in almost pure growth when cultures were taken, while repeated cultures of the urine and two blood cultures gave a growth of *Staphylococcus aureus*.

One chronic mild infection may influence the course of other chronic mild infections. For example, tonsils that appear to be chronically inflamed often become smaller and appear relatively normal after the eradication of severe oral sepsis. Chronic infection of the nasal sinuses may often be reduced in severity or apparently cured by the removal of infected tonsils or alveolar abscesses. Persistent cases of pyorrhea often yield rapidly to treatment after the removal of chronically infected tonsils or after the extraction of abscessed teeth. A patient who had been subject to recurrent attacks of slight jaundice associated with slight fever and pain in the region of the gallbladder for several years was apparently relieved permanently by the extraction of one abscessed tooth. Numerous similar examples with which careful observers are familiar could be mentioned.

EFFECT OF CHRONIC SEPSIS ON SYPHILIS OF NERVOUS SYSTEM

The ill effect of chronic sepsis on the course of syphilis of the nervous system is often very great, and on account of its practical importance will be dealt with in some detail. Syphilis of the central nervous system was suspected clinically and verified by lumbar puncture in 6 per cent. of 1,000 cases in office practice in which I made examinations on account of general medical complaints. One or more additional chronic infections thought to be of serious moment were found in nearly all of these. The coexistence of syphilis of the nervous system and chronic sepsis in persons observed in office practice is therefore common and very important. The fact that an infection in no wise related to syphilis may hasten the course and augment the symptoms of tabes dorsalis is well illustrated by the subjoined cases:

---

* A portion of this article has been reported in brief by the writer in a monograph entitled "Oral Sepsis in Its Relationship to Systemic Disease."

Case 1.—A man, aged 35, had been treated two years for tabes dorsalis. Before treatment was started he had noticed slight ataxia and bladder disturbance and was subject to mild attacks of darting pain in the legs. He improved very satisfactorily under specific treatment, and after he had been free from pain and bladder disturbance for more than a year, he had an attack of acute tonsillitis. With the onset of this there followed a recurrence of the most severe lightning pains that he had ever experienced. Morphin and salicylates to the limit were required to keep him out of agony. Nothing was disclosed except the attack of tonsillitis to account for the sudden recurrence of severe symptoms of tabes. A tonsillar abscess developed, and when this was incised, the lightning pains at once ceased almost completely. A few slight pains were noticed until the tonsils were removed three weeks later. During two years since that time, the patient has been practically free from any active symptoms of tabes dorsalis and has required very little treatment of any kind to prevent recurrence of his previous symptoms.

Since observing this case I have made a careful search for chronic sepsis in patients with syphilis of the nervous system, and on finding it have eradicated it thoroughly before beginning antisyphilitic treatment. It has seemed apparent from the results obtained that many of the symptoms of early tabes dorsalis that one might attribute to progress of the disease, such as lightning pains, increasing numbness, paresthesia, ataxia and visceral disturbances, may be rendered worse by chronic sepsis and may be relieved to a considerable degree by its removal. In fact, one might assert, with reason, that in persons suffering from tabes dorsalis the removal of chronic sepsis as a therapeutic measure for arresting the disease ranks in importance barely second to specific medication itself.

Case 2.—A man, aged 50, with taboparesis, had been given thorough specific treatment for years. When he came under my observation he was unable to attend to business, and spent most of his afternoons in bed. All known methods of treatment had been pushed to the limit, and it appeared that very little improvement could be expected from further specific measures. The patient had large tonsils and several abscessed teeth. These were removed, whereupon the patient improved steadily and to an unbelievable degree. Within less than a month he was able to engage again in business. He has continued mild specific treatment, and has remained in active business since that time.

Case 3.—A man, aged 45, was brought in with a diagnosis of tabes dorsalis. Physical and laboratory examination left no doubt concerning this. The onset had been stormy, and for three weeks the patient had been fairly convulsed with darting pains and had hardly been able to control himself. He was so nervous and irritable at the time of the examination that it was almost impossible for him to remain quiet long enough to permit a specimen of blood to be obtained for examination. Lumbar puncture could not have been performed without general anesthesia. The teeth showed an advanced degree of sepsis. The abscessed teeth were all extracted. Within a few days the patient's condition was so much improved that he went back to work. He felt and acted like a well man even though specific treatment had not yet been administered.

Many cases similar to the foregoing could be cited. These are not unusual cases, but represent almost an average experience.

ALLERGY

The problem of multiple infections and the relationship which one infection bears to another is deeper and of greater interest than the simple fact that a person bombarded by two or more infections is worse off than if he had only one. One infection has an interesting relationship to other infections with which a person may be affected, and may be explained in part at least through phenomena described under the terms allergy, protein sensitization and anaphylaxis.

A true toxin is not formed by any of the microorganisms that ordinarily take part in the pathology of infection in human beings with the exception of tetanus and diphtheria bacilli. Killed cultures of all other organisms or extracts of the organisms, or the culture mediums in which they have grown may be injected in large quantities into healthy guinea-pigs without immediate gross ill effect. They differ strikingly in this respect from tetanus and diphtheria bacilli, each of which produces a true toxin that is poisonous in high degree when administered subcutaneously even in very minute doses to animals. The products formed by other organisms that cause disease may be extremely toxic, however, through an entirely different mechanism, namely, the development in an individual of a condition known as allergy. This term, introduced by Pirquet, is used to designate the changed condition of human beings or animals, caused by infectious diseases or produced by inoculation with alien proteins, which causes the individual to react in a peculiar way if the bacteria responsible for the infectious disease or if the protein with which he may have been inoculated is reintroduced into the circulation. The ensuing reaction is in some respects protective and beneficial, but in other respects may be harmful and even dangerous.

Allergy and its effects are well illustrated by the action of tuberculin. Killed tubercle bacilli or their extracts, or mediums in which tubercle bacilli have grown, may be injected in large amounts into normal untreated animals without gross immediate ill effect. If even minute quantities are injected into animals or persons with tuberculosis, however, the effect is entirely different. Instead of its being apparently inert it causes a reaction which may result quickly in death. The changed condition of the animal produced by the tuberculous infection which renders it sensitive to the products of the tubercle bacillus is the condition known as allergy. Several striking phenomena follow the introduction of tuberculin into tuberculous persons or animals which never appear in the nontuberculous. These are, first, pain, swelling, redness and sometimes necrosis at the site of inoculation. This is known as the local reaction. Second, a rise in temperature and pulse rate and general symptoms of toxemia, which phenomena are known as the general reaction. Third, inflammatory changes at the site of all active tuberculous lesions. This is known as the focal reaction. This last phase is very interesting and may be used in explaining many of the phenomena observed in multiple infections. It may be slight or may be well marked. It may hasten the breaking down of tuberculous tissue and lead to rapid spread of the disease.

Some persons with tuberculosis become so sensitive to products of the tubercle bacillus that amounts of tuberculin as minute as 0.001 mg. are sufficient to produce severe reactions and to cause local inflammatory reactions at the site of all active tuberculous lesions. Others tolerate larger amounts. A reaction as described above can be produced in tuberculous animals by the subcutaneous injection of living tubercle bacilli as well as by extracts of the organisms. If tuberculous guinea-pigs are inoculated with living tubercle bacilli, a local and general reaction results within a few hours essentially similar to the reaction produced by the extracts of dead bacilli. If nontuberculous animals are similarly inoculated, no such reaction ensues, but the animal after a period of days or weeks becomes ill and dies of tuberculosis. If a localized tuberculous lesion in human beings (such as a tuberculous joint) is subjected to massage and manipulation, living tubercle bacilli or their products gain entry into the circulation, and a transitory rise of temperature and other symptoms of a general reaction may follow. This may be associated with an increase in the inflammatory reaction at the site of all other active tuberculous lesions (focal reaction).

The foregoing well known facts regarding tuberculous infection and the sensitization produced by it are true of infections in general. An attack of typhoid, for example, renders an individual sensitive to the protein of the typhoid bacillus, an attack of furunculosis renders one sensitive to *Staphylococcus aureus*, etc., so that persons having these diseases usually show a local, general and focal reaction if they are inoculated with killed cultures of the offending bacteria. This may temporarily increase the severity of the infection, the degree of which would depend to a certain extent on the quantity of bacteria injected.

Persons with chronic furunculosis may give a general reaction within a few hours if they are inoculated with an excessive quantity of killed staphylococci, and the furuncles are made temporarily worse. Such persons react similarly when they are subjected to the effect of an increased number of living bacteria due to the development of a fresh furuncle. This often causes both a general and a focal reaction. For example, with the development of a fresh furuncle there may appear fever, malaise, etc. (general reaction) and an exacerbation in the inflammatory process in recent furuncles (focal reaction). In fact, signs of activity, such as itching and redness, may appear in the scars of recently healed furuncles. This may be followed by a discharge of pus containing *Staphylococcus aureus*. These well known principles are true of infection in general and can be used in the explanation of many interesting phenomena. It often explains the reason why with the onset of a new infection signs of irritation and inflammation may appear within a few hours at remote points. Case 4 illustrates this:

CASE 4.—A woman, aged 60, relatively normal for her age, had ten infected teeth extracted. Less than twenty-four hours afterward there developed a severe acute follicular tonsillitis. Several days later the infection began to spread from the gums to the cheeks, pharynx and tongue, and give rise to an extensive ulcerative stomatitis. The point to be emphasized here is the fact that the inflammatory reaction in the tonsils, while relatively distant from the gums, occurred within a few hours and preceded by several days the infection of the neighboring tissues of the mouth. It occurred after too brief a period of time to be the result of direct infection of the tonsil by the organisms disseminated from the alveolar process, and must have been a reaction of tissues sensitized by the organisms already localized in the tonsils. It was analogous in every way to the focal inflammatory reaction in the lungs that may be brought about in tuberculous individuals by the injection of an overdose of tuberculin.

It is by no means uncommon to observe pain in the region of the gallbladder, appendix, stomach, joints, cervical glands, etc., a few hours after the extraction of infected teeth, and such may frequently be interpreted as focal reactions caused by the traumatic dissemination of micro-organisms or their products from the alveolar process.

Frequently the clinical manifestations of chronic appendicitis, cholecystitis, gastric and duodenal ulcer, chronic arthritis, etc., clear up rapidly after the extraction of diseased teeth, even though the first effect may have been an increase in the inflammatory processes. Occasionally chronic inflammatory conditions that appear to indicate the need of surgical interference and serious internal diseases that cannot be reached by therapeutic agents partially clear up after as simple a procedure as the extraction of a tooth or the removal of a pair of diseased tonsils. The relief can often be attributed to the fact that sources of bacterial products that have been continuously causing focal reactions in the infected organs have been removed.

This explanation applies very nicely to multiple infections when each lesion is caused by the same micro-organism. It may or may not apply in part to lesions caused by different micro-organisms. This question is an open one about which much might be said. For example, if a person has streptococcic tonsillitis, a latent streptococcic infection in the joints and in the gallbladder, it would be in harmony with accepted theories if an acute exacerbation of the tonsil infection were followed in a few hours by a reaction in the joints and gallbladder that caused pain and other phenomena of a focal reaction. This explanation, as previously mentioned, would not apply in the same way to multiple infection if the various lesions were caused by different micro-organisms, because sensitization against the protein of an infecting organism is thought, and I believe correctly, to be more or less specific. Whatever the theoretical explanation may be, we have this fact, which is beyond dispute: Infection with one micro-organism may lower the resistance against other micro-organisms to a degree that is by no means negligible. I dealt with this above, and mentioned clinical examples. One further illustration even more striking may be added here:

CASE 5.—A patient, aged 35, apparently in good health, had a severe attack of erysipelas, evidently streptococcic in origin. A few days after this a very insignificant pustule no more than 2.5 mm. in diameter which showed *Staphylococcus aureus* on culture began to spread with great rapidity and within a few days gave rise to an extensive phlegmon which persisted for two weeks. In this instance the streptococcic infection certainly had lowered resistance against *Staphylococcus aureus.*

TYPES OF IMMUNITY

There apparently exist two types of immunity—a specific immunity and a nonspecific immunity. Nonspecific immunity has been made use of in the cure of disease by Miller and Lusk, Jobling and Petersen and others, who have injected alien protein of different types (including killed typhoid bacilli) in the treatment of arthritis and other infectious diseases. While the results obtained were not invariably a complete success, they were sufficiently striking to warrant the observers in concluding that nonspecific immunity is often an important factor in the cure of disease. The inoculation of infected persons with an alien protein, such as typhoid bacilli or albumose, may cause general reactions that render the patient's condition temporarily worse. Often it also causes focal reactions in the infected areas. For example, in persons with arthritis the joint pains may often be more severe a few hours after the intravenous injection of typhoid bacilli. Persons with tabes dorsalis frequently have sharp, darting pains in the legs after similar intravenous injections. The reactions that are produced by the injection of alein proteins are often very similar to reactions that follow inoculation with the specific organism that causes the person's disease. It is not inconceivable that frequently repeated inoculations with a nonspecific virus might cause repeated reactions in inflammatory lesions due to other organisms and in this way do harm and cause an exacerbation of the disease. It is possible that one infection may exert a deleterious influence on lesions caused by other micro-organisms in some such way as this and might in part explain the cure of one infection by the removal of another infection in no wise related to it.

PRACTICAL CONSIDERATIONS

This paper has been written because of its practical bearing on the treatment of infections. Whether or not the explanations given are the correct ones, these facts stand, I believe, proved and beyond dispute: 1. In persons suffering from multiple infections, each infection may increase the severity of the others whether due to the same or to different organisms. 2. Removal of one infection may, under favorable conditions, be followed by spontaneous healing or improvement in the others. A physician often is faced by a combination of infections, some of which are removable, and others not. A consideration of problems of the relationship between infections often aids in the practical handling of the situation. If minor infections are promptly taken care of, those that are more serious may take care of themselves.

CONCLUSIONS

1. When a person has several infections, each may increase the severity of the others whether due to the same or different infecting micro-organisms.
2. Acute exacerbation of one chronic infection may stir up other apparently latent infections into activity.
3. The removal of one infection may under favorable conditions be followed by spontaneous healing or improvement in others.
4. If minor infections are properly taken care of, those that appear serious may yield more easily to treatment.
5. Chronic sepsis exerts a serious influence on the course of tabes dorsalis, and its removal is frequently followed by amelioration in the symptoms of this disease.

Effects of the War on the Next Generation.—The general physical standard of the men who have joined the colors is necessarily on the average distinctly better than that of the men who have not joined. Only men above a certain level of physique are accepted; men of smaller build or weaker constitutions are rejected. A heavy loss of life has occurred, and is yet to occur among the men who are fighting with our armies. No corresponding wastage is occurring among those who are not fighting. The result must be that the average physical standard in this country of males of the ages of say 20-40 will be much lower after the war than it was before the war. This lowered standard will be reflected in children born in subsequent years; and will begin to be recorded at school medical inspections about the year 1921, when the children born in 1916 are entering on their school life.—Dr. D. Morley Mathieson, M.O.H., South Shields, England, *Medical Officer.*

THE TREATMENT OF LYE STRICTURES OF THE ESOPHAGUS*

THOMAS HUBBARD, M.D.
TOLEDO, OHIO

In 1910, Dr. Jackson made earnest appeal for legislation to protect innocents from lye products sold for domestic use. Careless and misleading labels and indiscriminate distribution of caustic cleansers have been responsible for many of these accidents and food and drug laws do not penalize the manufacturer or agent. They are put on the market to be used by housewives and certain it is that the more careless the housewife the more likely she is to use the stuff and, also, the more liable she is to have more children than she can safeguard.

These overworked women and their children deserve what protection the law can give them against the commercial shark and it seems to become the duty of the medical profession to keep hammering away until they are heard. Caustic alkalis and cleansers should be caution labeled and the sale restricted as are all poisons.

There are a few important features of lye corrosion which should be mentioned. The mouth secretions usually protect by dilution the throat and hypopharynx and, as a matter of clinical observation, the real escharotic effect is usually in evidence at the cricoid or about the depth of the bronchial region and above the hiatus.

It seems that at these points the caustic is arrested briefly, or owing to the somewhat delayed spasm excited by the irritant, the bolus is retarded in the lower esophagus and enters the stomach slowly. This accounts for the fact that comparatively few of these victims exhibit stomach lesions, the acid secretions neutralizing as fast as it reaches the organ. The esophagus is a senseless kind of an organ, that is to say, deficient in sensible nerves and inclined to throw spasmodic fits much to the detriment of its own welfare. But we must label this a conservative physiologic action in that it aids in protecting the more complex, vital organ, the stomach. Most of these victims vomit rather promptly and thus does the stomach repay the self-sacrificing esophagus by furnishing the antidote, acid secretions.

CASES OF LYE TRAUMA

I have seen two fatal cases which I will briefly mention to make clear the serious effects of lye trauma in the stomach.

One, a lad, aged about 12, who had swallowed lye at 2 years of age. The stricture was not complete and he had existed on liquid nourishment for ten years. He was diminutive and emaciated to a skeleton—no hair, no teeth, a pitiful little old man. Gastrostomy was done and an effort made to build him up before dilatation of the stricture was attempted, but there was evidently atrophy of the gastric mucosa, and he died in about a month from inanition.

The other fatal case was that of a girl of 5 years who had swallowed lye six months previously. The stricture of esophagus was of moderate degree, but she could not digest anything and died in a few weeks of inanition.

A third case is reliably reported to me. Lye was swallowed at the age of 5. No esophageal lesion followed, but life has been a wretched existence well into manhood. He suffers from malnutrition, poor development, bad teeth, etc., due probably to lye destruction of the gastric mucosa.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

The youngest patient I have treated for lye stricture was a baby 1 year old. He had eaten a lump of caustic powder sprinkled on the floor preparatory to a scrubbing. The stricture was in evidence about two months later, located near the cardia. The usual roentgen-ray barium examination, followed by the Sippy wire guide under esophagoscopic control, and then gradual dilatation over a period of about two months effected apparent cure. This family left town and I cannot give the end result.

I have seen just such cases in older children and adults with moderate strictures and big dilatations above having obstruction to deglutition periodically when retained food caused increase of inflammation at the site of stricture. These cases should be watched over a period of years.

The next case presents unusual features, in that the strictures involved the lower 3 or 4 inches of the esophagus and the canal was very tortuous, with small sacculations between constrictions. This was shown in the roentgenogram, and esophagoscopic control in the early period of treatment was very difficult because of the impossibility of passing a tube below the bifurcation level.

This lad of 6 had swallowed lye eight months previously and the esophagus had been occasionally bougied roughly, but finally it had closed tightly. No liquids had passed for four days and he was sent in to the hospital by the family physician for gastrostomy.

Under esophagoscopic control, I passed several whalebone filiforms down and got one through; then a larger bougie and finally a small catheter which was left in, fastened to the teeth. Through this he was fed for two days and on removal he swallowed liquids fairly well, but it soon closed, and again the filiform method had to be repeated.

On account of the dilatation and sacculation above the first stricture, it was impossible to get the Sippy wire guide through without the aid of the esophagoscope, and, as a lad of this age, and Scotch at that, naturally and forcefully resented a steady diet of metal tube, I resorted to the braided string method. It took about five days to get 7 yards down. Any shorter length than that (there was probably some snarling) did not give firm enough anchorage to keep the olive guide in the tortuous passage.

(Experiences in water hunger and starvation nerved this lad of 6 up to willingness to aid in the work, and he played about with the spool pinned to his jacket, and his mother daily cut off a few feet which passed clear through. I mention these details because this heroic little fellow deserves it. Few would tolerate it. His companions learned to appreciate his courage and more than one newcomer got a good thrashing for making fun of him.)

Two weeks, with dilatation every other day, brought the lumen up to 29 (F.). Progress was very slow in this eight-months-old multiple stricture.

Even after that it was difficult to avoid entering a saccule. For two years the dilatation was held at 31 (F.) and I considered him cured and with prospect of a perfectly useful esophagus, provided it was occasionally dilated as he grew. At about the age of 9 he died of acute septic meningitis, being sick only four days.

Was gastrostomy indicated in this case after the four days' starvation? It was probably more of a venture to attempt dilatation with possibility of failure than to have done gastrostomy with certainty of getting fluid into the stomach. The conclusion is that in patients exhibiting extreme water hunger, prolonged effort to enter the stenosed esophagus should be avoided and preparations for prompt gastrostomy should be the rule. The string method is not practical because of lack of time.

A little Welsh war baby, aged 2 years, has been under treatment for six months now. She was starving four months after drinking diluted lye. Water hunger was extreme, stools were like chalk and she was emaciated to the limit.

The stricture area begins at the bronchial level and extends to the cardia, three distinct stricture bands being in evidence. For the first month it was necessary to pass the guide through the esophagoscope. The first few dilatations, under light anesthesia and with aid of the esophagoscope, were comparatively easy, but frequently after that it was difficult to pass the guide even though she swallowed liquids readily. There is a crescentic band at the bronchial level and some dilatation above it. In a comparatively recent case like this the difficulty was probably due to softened sloughing mucosa into which the guide would plow.

In all such cases, one must use the esophagoscope and take unusual precautions to avoid perforation until a free straight passage is well established. The dilatation intervals are too long in this case, as the patient lives out of town and progress is slow—now held at 26 (F.) for six months.

DILATATION AFTER GASTROSTOMY

The worst case I have encountered and the one that presents some special features for discussion is that of an adult who swallowed about half an ounce of concentrated sodium hydroxid in an attempt to establish siphon flow by mouth suction through a large rubber tube. Himself a chemist, he was so choked and shocked by the accident that no neutralizing antidote was taken. Spontaneous emesis soon after probably saved him from fatal consequences.

I first saw him about three weeks after the accident and soon thereafter passed the esophagoscope. The throat and hypopharynx were quite denuded of epithelium and a stricture web was forming near the cricoid. This was easily passed, but at the bronchial level the esophagus was nearly closed by edema. Below this, all was macerated and the mucosa peeled off before the tube, or bougie.

There was still considerable pain deep behind the sternum, and it was evident that it was a very serious trauma. No sound was passed, as he was getting sufficient fluid through, and it was decided to try rest and sterile liquid food with local medication to reduce the inflammatory swelling. Bismuth carbonate and argyrol was given, and, to allay spasm and pain, orthoform in emulsion was swallowed prior to taking fluids. Under this treatment he improved.

Three weeks later I succeeded in passing a small tube down to about 2 inches from the cardia, but I could not get even a filiform through the softened, bleeding lower esophagus. Roentgen-ray barium examination about this time was instructive. A fine, narrow thread gravitated into the stomach. In such serious cases it is important to determine the degree of muscle involvement. It would seem that by this means the deglutition muscular activity may be studied. Deep destruction of esophageal wall, including muscle, increases liability of perforation and also affects the prognosis.

Possibly I delayed too long before attempting the string guide method, and this was also unsuccessful. He had acquired the regurgitant habit, and, after getting down a yard or so, would promptly regurgitate, even though fluids passed into the stomach.

Absolute closure came rather suddenly, probably being due to exfoliation of the lower 5 inches of mucosa, and gastrostomy was done to save him from starvation, about four weeks after I first saw him. It was a perfect operation, performed by Dr. Lewis Smead, and three weeks later he was in normal strength and working regularly. Having failed to get the esophagoscope below the bronchial level, I tried to pass the guide from above under fluoroscopic control and failed. Dilatation from below was successful; that is, I passed the bougie —a urethral sound of proper curve—up to 10 inches from the incisors to the upper stricture.

Then I again dilated the firm stricture at this point from above through the esophagoscope and finally succeeded in getting the wire guide through the 5 inches of tortuous canal. Whole plaques of softened mucosa came away with each operation of passing the olives.

Gradually dilatation was accomplished up to 37 (F.), at which we now encounter rather firm resistance, in the form of about four stricture bands in the 5 inches, the worst being at the hiatus.

Was the resting of the esophagus overdone in this case? Probably a bougie could have been passed early, but at the time I first saw him the tip of any bougie seemed to bury itself in any direction in the sloughing tissue, and as submucosa and possibly muscle seemed involved, the indications were to avoid extra trauma. Gastrostomy should have been done two weeks earlier and then the string guide method would not have failed.

Retrograde dilatation seemed very easy on first trial, but on a second and a third attempt with a longer bougie of same curve, I could not find the orifice. Probably this was due to irregular stomach contraction combined with cardia spasm.

METHODS OF DILATATION

Now a few words about the Sippy method. For safety and precision it seems to me ideal. The essentials of the technic, as I have found by experience, are as follows: First, know your measurements; second, be sure that you are well into the stomach with wire guide and then go clear through with the properly selected olive bulb on the cable. If you try too large an olive and fail to get through you may pinch a band of stricture tissue between two of the olives on extraction—rather risky but even at that sometimes beneficial.

The successful dilatation of strictures of this class makes possible but does not insure a cure. The work is only half done. With starvation threatening, these patients are very obedient, but they are liable to neglect subsequent treatments and, every time a stricture tightens up, the tissue is more firm and unyielding. It is important to decide on the maximum dilatation, hold it there, and in children try to keep up with growth. It should be 26 in a 3 year old child and from 35 to 40 in an adult.

I have in mind a rule which establishes the maximum. Dilating olives are graduated on the 1 mm gradation. It usually takes about three stretchings before the olive will pass easily, warranting increase in size the next time. When one has reached a degree of dilatation that allows normal deglutition, one may determine the maximum in that particular case by this test. If five or six dilatations at short intervals bring no improvement, that is, resistance does not yield, the probability is that one has reached the limit. This should be controlled by roentgen-ray bismuth study to determine the amount of dilatation above the stricture (Jackson).

With forcible dilatation of strictures, I must say I have had little experience. In single strictures of limited area, forcible stretching seems indicated. But in lower tortuous multiple strictures with intervening sacculation, such as we usually have in lye cases, it seems to me quite impracticable and even hazardous. The element of danger lies in the fact that the weakest spot will yield first. In crescentic folds this means perforation.

I am in favor of holding the maximum dilatation by passing a specially adapted olive bulb at frequent intervals. This seems better than the flexible bougie. One knows positively when one is through the stricture. With the flexible fiber bougie one is never quite sure, especially in children.

In gastrostomized cases, the stomach tube should be retained even after dilatation is well advanced to give confidence to the patient; and also, in case there is any considerable trauma from dilatation, the esophagus may be rested by direct feeding until inflammatory reaction has subsided

DANGERS AND LIMITATIONS

At best the work is tedious and slow and there is always an unknown element of danger. Much depends on the intelligence and cooperation of the patient. And as lye trauma occurs chiefly in the very young, it is certain that some of these cases are permanently injured and more or less handicapped for life.

There is liability of unwise restriction of diet. The natural habit is to select only soft, easily masticated foods. This results in malnutrition and retards development of teeth, bone and muscle. These unfortunates may be allowed to eat all kinds of food if only they are trained in the art of proper mastication.

Now it is not a surgical triumph to prolong a wretched existence. We must see these patients through and try and make the end-result creditable to the art.

ABSTRACT OF DISCUSSION

Dr. Chevalier Jackson, Philadelphia: It does seem too bad that in practically all of the states of the Union, if a druggist sends out caustic alkali he is compelled to label it, to put a skull and cross-bones on it, giving an antidote; and that caustic alkali is put on the medicine shelf. Next door to the druggist the grocer can sell caustic alkali which goes into the kitchen and is used for dishwashing and various other purposes about the kitchen, but it is not required of the grocer that he put one word on the package as to the poisonous nature of the contents. If there is any mention of poison at all it is so small as to be altogether inconspicuous. This should be regulated by law.

Many other interesting points were made by Dr. Hubbard, but I shall take time to refer to only a very few of them. In regard to the stomach being unaffected, it does seem strange that so little harm is done when caustic fluid goes down into the stomach. I saw one case in which the patient had a pyloric stenosis as well as an esophageal one. It was thought that the pyloric stenosis was due to the effect of caustic alkali; but it seemed to me doubtful. We came to the conclusion that there had existed a congenital pyloric stenosis and that it had increased; but was not due primarily or secondarily to the caustic alkali. In regard to trauma from faulty bouginage, the French clinician, Trousseau, in the pre-esophagoscopic days, said that sooner or later patients with esophageal stricture died of the bougie. Why? Dr. Hubbard referred to a cicatricial band. He knew what the local conditions were because he had looked at them. Blind bouginage is dangerous. Safety necessitates a slow procedure under the guidance of the eye.

Another point that I wish Dr. Hubbard would make reference to in closing is how soon after the accident we ought to use the esophagoscope. I feel reluctant to use it soon. It should be decided whether we should pass the esophagoscope at once and institute the treatment Dr. Hubbard suggests, or wait for three or four weeks. Another point is that in these cases there is nearly always an intermittent difficulty in swallowing. These people will go along with little trouble apparently for awhile and then for perhaps two days at a time they cannot swallow anything, as a result probably of esophagitis or the lodgment of food, or both. In regard to dilatation, the matter can be summed up in a few words—that with the rapid method the outcome will be a few brilliant cures but a very high mortality. Esophagoscopic bouginage is safe, but it is very slow.

DR. F. KEIPER, Lafayette, Ind.: One case which I have just finished treating temporarily (I say "temporarily" because very often these strictures have to be dilated again), was in a child, three years of age, who had swallowed only a thimbleful of lye. When I examined that esophagus I found about three inches of a very tight stricture at the cardiac end of the stomach. I believe that in all these cases the first thing to do is to have two roentgenograms, one laterally and one anterior posterior, because they give valuable information that we ought to have in the subsequent dilatation of these strictures. Then, again, no examination should be complete unless the esophagoscope is passed. It is surprising how much assistance this gives sometimes. By passing a large esophagoscope you dilate the esophagus more or less, so that on looking down through the esophagoscope you will be able to find the point of entrance into these very narrow strictures. In this case the stricture was so small that it would accommodate only the smallest of the Jackson filiform bougie, on the end of a long steel rod and then with great difficulty. I attempted to pass a Jackson bougie that carries a string, but I was unable to get through because it is a stiff steel bougie. Then it occurred to me to perforate the filiform and use that as a means of passing the string through the stricture, and I was successful in working the string back and forth through that, and cut the stricture. Of course we get but little help thus but it all counts. Patients will ask, how many dilatations will have to be made; but we cannot tell; it may require fifty or sixty and maybe more. I do think, however, that nothing should be passed, not even a filiform bougie except with the esophagoscope in place.

Another point brought out by the essayist is that it is not necessary to anesthetize the patient. This can be done without any anesthetic whatever. Of course, these little patients require to be restrained, by wrapping them tight in a sheet or blanket and then held by an assistant in order to make the first few passages, but after awhile when the patients understand better we do not have much trouble.

There is another class of burns seen sometimes among farmers when they use hydrochloric acid to burn off warts on cattle. Every once in a while some child takes a drink of that stuff. I have seen two cases where children had been sent to me in order to have the esophagus dilated, because of regurgitating of food, but in those cases I never found a stricture of the esophagus. The hydrochloric acid evidently damages the mucosa of the stomach very seriously. Whenever I find a case of this kind the only thing to do is to turn the patient over to a competent internist in order that they may have the proper care and nourishment.

JOSEPH A. STUCKY, Lexington, Ky.: I have had four cases of stricture of the esophagus as the result of swallowing lye. A few years ago when Dr. Jackson first called attention to this matter I suggested that each one of us consider himself a committee of one on publicity and get in touch with the newspapers, having them say something about it. I am sure that in the last year I have seen a fatality as the result of too much force in passing the bougie. I had seen this child the day before, after giving it some bismuth. It passed out of my hands, but a few weeks later I saw an attempt made to use a bougie. I know that it went through and the child died. We should not only use the greatest care, but we should operate by sight alone. Now that we have the roentgen ray and the fluoroscope there is no excuse for our not seeing what we are doing. In two of my cases there has been involvement of the pylorus, and in order to sustain my patients I had to get the assistance of a general surgeon and have the stomach opened and feed the child that way.

I hope that the attention of the public will be called to this and that the grocer as well as the druggist be obliged to label lye.

DR. GEORGE F. COTT, Buffalo: A few years ago I reported sixteen cases of stricture of the esophagus. You have heard the sad side of this, but there is also a bright side. A little boy, about two years of age, who had swallowed some lye, came into the hospital and after several attempts to pass a small bougie it was given up. A woman connected with the hospital took pity on the boy and adopted him. He is now enjoying all the luxuries of wealth—that is one of the bright sides.

DR. WILLIAM B. CHAMBERLIN, Cleveland: One thing Dr. Hubbard failed to mention is the decided value of the Jackson two-pronged dilator, which has a very narrow tip. It can be inserted easily into a very small stricture, provided, of course, that you are able to get the filiform through and realize this is the true opening. In my hands this instrument has proved of very great advantage.

DR. JOSEPH C. BECK, Chicago: I have under my care at present a case of trauma of the esophagus, an acute condition which I believe I was instrumental in bringing about. A man weighing 200 pounds came to me with a history that he had had more or less difficulty in swallowing for a year, and this difficulty is increasing so that at times he has considerable difficulty in swallowing saliva. I noticed that the man had a very severe burn on the hand which dated back before the years when he had trouble with his swallowing. In other words, I suspected that this was a case of stricture of the esophagus that we are apt to see following certain conditions of the external part of the body. At any rate, the esophagoscope was passed behind the cricoid and below that the puncture was made. I suspected carcinoma, but when I looked I found a quantity of liquid, like soup, with a little solid food in it. I sucked that out and used the fluoroscope and roentgen ray. The diagnosis was made, but the interesting point is the complication. The man's esophagus closed up so that he could not get any food down. This was seven or eight days ago and he has not had any food, except through the rectum. I consulted a surgeon in this case, but he would not do a gastro-enterectomy in this case as he believes the man is well nourished and does not need this treatment. The next day the urinalysis showed sugar; he probably had it right along. In diagnosing these cases the important point is the examination.

DR. C. C. KNEEDLER, Pittsburgh: Dr. Hubbard spoke of one of his cases as an ambulant case. Do you not consider them all hospital cases?

DR. EUGENE LEE MYERS, St. Louis: A child accidentally swallowed concentrated lye. After prompt antidotal treatment by Dr. A. H. Juengel of St. Louis, the child was brought to me for the difficulty in swallowing. In due time an attempt was made to do an esophagoscopy which revealed three strictures, the lowermost being very difficult of dilatation. The instruments that I tried to use were of no avail. I was in great fear of perforation, as every attempt I made with the bougie would bring the bougie with a turn to the left, and I realized that I had a tortuous channel. I then proceeded to treat this stricture similarly to strictures of the urethra, using glycerin and olive oil as an emollient. I made use of the smallest Killian tube, which has an obturator. With the greatest of care I passed the stricture and removed the obturator and was pleased when the bougie slipped through the tube into the stomach. I then removed the tube, leaving the bougie in situ, after the principle used in leaving a filiform in the urethra. The child was in good condition at that time, but on my return to the hospital that night imagine my surprise and chagrin to find the little one with a temperature of 104 F. and pulse of 170, apparently moribund. I was of the belief that I had punctured the esophagus, but careful examination with Dr. Thomas W. Taylor and Dr. A. H. Juengel brought out the fact that the child had a double pneumonia, the cause of which could not be laid to the anesthetic, as chloroform was used.

Questioning the mother brought out the fact that the child had a severe chest cold previous to the instrumentation and it is probable that our working in the esophagus for the length of time that I found it necessary (two hours) caused the pneumonia to develop. After several dilatations in the office, the family discharged their child, claiming the boy was eating to their satisfaction, notwithstanding all my efforts to have him bougied at intervals. At the time of my last inquiry the boy was still eating everything without any signs of a stricture.

Dr. Thomas Hubbard, Toledo, Ohio: With reference to legislation, I would say that some years ago, soon after Dr. Jackson's paper appeared, the Bureau of Chemistry and the Department of Agriculture undertook some legislation in this regard, but it evidently has been hanging fire and nothing has been done. But I think that this organization, with the assistance of the Council on Pharmacy and Chemistry, can push it through. Many of these matters suffer delay through indifference and not positive opposition.

How soon to pass the esophagoscope after trauma? That it a very important question. In the last case I passed it three weeks after the trauma. At that time it looked like a ruined esophagus. As a factor in lessening the trauma, a light anesthetic is needed in most of these cases, especially in children. Sometimes sudden closing of the esophagus is caused by exfoliation of the mucous membrane which peels off and plugs the tube. That is what occurred in the case mentioned. Gastrostomy became urgent. In cases where the patient has been known to swallow lye and there is no esophageal lesion, watch out for gastric lesions. The longer the detention in the esophagus the less likely there is to be stomach disturbance. I have had no experience with the Jackson dilator.

I do not think we should consider all of these cases hospital cases. Just as soon as the acute stage is over they ought to be treated and trained at home. The adult and the child has to be trained and you might as well begin it early. They have to be instructed as to the selection and mastication of food, consequently I think they are home cases just as soon as the more important instrumentation period is over.

THE NATURE OF SURGICAL SHOCK AND HENDERSON'S THEORY OF ACAPNIA *

A. OSORIO DE ALMEIDA
Professor of Physiology, Medical School of Rio de Janeiro
AND
MIGUEL OSORIO DE ALMEIDA
Professor of Physioloogy, High School of Agriculture
RIO DE JANEIRO

The problem of shock is at present the direct object of energetic research in various scientific laboratories of the United States. The purpose of this research is to determine in the briefest possible time the true nature of this peculiar condition. The urgent need for such investigation is easily understood in view of the fact that large numbers of wounded soldiers are constantly being lost through our inability to treat cases of this nature successfully.

Before the war, the question of shock had been studied in detail, and distinguished among the publications presented on this subject are those of Yandell Henderson. Some time after the appearance of Henderson's work in which the theory of acapnia was advanced, we had occasion to conduct a series of experiments in order to verify the findings of the American physiologist. A paper[1] dealing with the results of these experiments was published in a French journal, but it appears to have remained entirely unknown to the American medical profession. Thinking that our past experience will now be of some value to other investigators, since all known factors bearing on the question of shock must be taken into consideration, we have decided to summarize briefly the most important observations noted in our former experiments.

There is no necessity for a detailed citation of Henderson's theory or a comprehensive discussion of the series of experiments from which he derived his conclusions, for it is well known that Henderson studied the effect of excessive artificial respiration on dogs which in many instances had the thorax open. These animals, after a period varying from one to three hours, presented a state identical to that condition known as surgical shock.

In experiments so conducted, there occurred the formation of accentuated acapnia, namely, there occurred a considerable reduction of the amount of carbon dioxid in the blood and also in the body tissues.

In his first work, Henderson designated the important part played by carbon dioxid as a hormone and after an extended and ingenious series of deductions, attributed to acapnia the responsibility for the production of the state of shock. One of the most remarkable points about his theory Henderson considers the fact that when artificial respiration is made in such a manner that the air already once breathed is immediately rebreathed, it becomes impossible to obtain shock. Now it is exactly under these conditions that it is impossible to have acapnia, notwithstanding excessive artificial respiration. Today Henderson holds his theory as fundamental and only admits little modifications of the details. Recent research has demonstrated the existence of a condition of acidosis in individuals suffering from shock. Henderson,[2] basing his views on modern revelations concerning the action of the ions of hydrogen, shows himself inclined to believe that this acidosis plays the part of a compensator of the acapnia, and it is able to produce the death of the individual through apnea excessively prolonged.

With Henderson, the question of knowing which of the two factors is primary, the acapnia or the acidosis, should be resolved in this connection by attributing the condition of acidosis to acapnia.

Our first experiments were intended only to verify that excessive artificial respiration actually produced a state of shock. This work was conducted in Rio de Janeiro, Brazil, during the summer of 1912. In numerous attempts, never was it possible to obtain anything that resembled the state of shock as described by Henderson. The artificial respiration was frequently prolonged for four or five hours or more, without the animals showing the slightest symptom that permitted us to think of it as being in a state of shock. In cases in which the thorax was not open, the animal, if taken from the operating table at the close of the experiment, continued to stand up or walked about, and showed itself to be perfectly conscious, although displaying unmistakable signs of great fatigue.

In the face of such negative results, it was immediately evident that there was present in these experiments a factor quite different from that encountered in the work of Henderson. A detailed examination of the equipment proved that it was quite the equivalent of that employed by Henderson.

[2] Henderson, Yandell; Prince, A. L., and Haggard, H. W.: Observation on Surgical Shock, The Journal A. M. A., Sept. 22, 1917, p. 965.

Therefore, only a foreign factor of importance could influence the results to such an extent. Furthermore, this unknown factor was easily discovered as being in the temperature and humidity of the air actually employed for respiration in the various experiments.

In Rio de Janeiro, the temperature of the air in summer frequently ranges from 32 to 34 C. (89.6 to 93.2 F.) during the day, and its percentage of humidity is always very high. Taking these conditions into consideration, we made the following hypotheses:

1. Excessive artificial respiration is able to produce different effects that vary in accordance with the character of the air employed.
2. The primary effect, already well known, is the formation of acapnia.
3. If the temperature and humidity of the air employed are high, there is no appreciable modification of the internal temperature of the animal.
4. If the temperature and humidity of the air employed are sufficiently low, a progressive internal cooling of the animal occurs.

In our experiments, there was evident formation of acapnia without the slightest change of the internal temperature of the animal, and, moreover, the state of shock did not occur.

The results already obtained seem sufficient to justify the conclusion that acapnia is not the cause of the state of shock that Henderson observed it to be. Then the thought occurred that if the artificial respiration was made with air having an approximate temperature of 18 C. (64.4 F.) and a percentage of humidity ranging from 30 to 40, the internal cooling of the animal would be sufficient to induce a state of coma. The importance of this question is significant when it is realized that the foregoing conditions of temperature and humidity are identical with those ordinarily encountered in the laboratories of the United States and Europe. As we did not know positively the particulars in this respect as to Henderson's experiments, it was permissible to suppose that these were approximately the conditions under which his investigations were conducted. Furthermore, if these conditions should prove sufficient to produce internal coooling of the animal up to the point of inducing coma, it would indicate that shock, as observed by Henderson was nothing more or less than this coma itself. A second series of experiments was directed along this line of investigation for the ostensible purpose of determining the truth of this supposition. Artificial respiration was applied with the same intensity as in the first series of experiments, but the temperature of the air was lowered to 18 C., and its humidity was reduced. The animals thus treated soon manifested a rapid fall of internal temperature, and this cooling process was carried to the point of producing a state of coma that terminated in death.

CONCLUSIONS

Without wishing to enlarge on the details of experiments already published, it is believed that the results of the experiments performed permit the following conclusions to be drawn:

1. Excessive and prolonged artificial respiration produces coma and death only when it is made with air having a sufficiently low temperature and humidity.
2. If the temperature and humidity of the air are sufficiently raised, the respiration may be prolonged indefinitely without obtaining this result.
3. Since the conditions described in the preceding paragraph produce strong acapnia, it is clear that this state has no relation to coma.
4. It was the coma resulting from the internal cooling of the animal that Henderson confused with a state of shock.
5. The continuous failure of Henderson to obtain what he thought was shock, when respiration was made with air already once breathed, proves that under such conditions it is impossible to obtain the internal cooling of the animal because expired air is saturated with moisture and has a relatively high temperature.

OCULAR HEADACHE *

J. W. CHARLES, M.D.
ST. LOUIS

The vagueness of the term headache leads the layman to describe almost any discomfort in the region of the eyes, which has no outstanding characteristic, as "headache." For example, reflex discomforts which bring the patient to the ophthalmologist for headache and which have no foundation in eye disease, such as errors of refraction, muscle imbalance, or a weak accommodation, are frequently caused by a conjunctivitis and are "cured" by lid treatment. Instances are seen in which pressure on the lids give instant, if only temporary, relief from this kind of "headache." These cases must be differentiated from those of deep pains in the eyes without redness, sometimes accompanied by headache, which make one suspicious of nasal sinus disease. These nerve reference pains in the eyes result most frequently from the ethmoids or the frontal sinus, and may be likened to the pain in the knee from hip joint disease.

While headaches from vision for distance alone sometimes occur in otherwise normal people who have ocular errors, these are much more often found when a strain is being forced on the eyes in near work. But headaches occur in so many persons who have only a slight error in refraction or a low degree of muscle imbalance as to force one to the conclusion that the eyes are acting only as an exciting cause which might not be at all effective, were the patient otherwise well and well balanced nervously. The result depends largely on the individual nervous system behind the eyes.

In 1907, Coggeshall and MacCoy[1] found from the study of 1,700 cases that "a neuropathic diathesis is an essential condition of the occurrence of almost all of the chronic headaches of the kind we are discussing," combined with some source of local irritation not otherwise manifested, often with an anemia or a toxemia; and frequently a combination of these causes occurs. The greater the one factor, the less need be

[1] Coggeshall, Frederick, and MacCoy, W. E.: Headache as a Symptom of Local Disorders, The Journal A. M. A., Jan. 4, 1908, p. 15.

the other. They also emphasized the fact that the local eye-strain may cause headache only when the patient is nervous from some other cause, for example, when the eye-strain headaches occur only at the time of the menstrual period. The deep dull headache from disease in the nasal sinuses may be combined with a muscle imbalance which is itself a reflex of the sinus inflammation. Or the occipital cases due to uterine or ovarian trouble may be aggravated by a muscle imbalance which is increased by the pelvic disease (Coggeshall and MacCoy).

The vicious circle of high blood pressure and pain may be observed in ocular headaches combined especially with the vascular hypertension caused by nervous contraction of arterioles. One of the finger-posts toward diagnosis in these cases is the surprisingly ready relief which often follows complete rest in bed, which does not so promptly reduce hypertension in organic vascular disease. Patients suffering from high blood pressure alone frequently consult the ophthalmologist for headache and discomfort in reading. No amount of change in the glasses will bring relief; and it becomes very difficult to convince such a person that it is necessary to consult an internist, even when one sees the characteristic changes of arteriosclerosis in the ocular fundi. Usually these hypertension headaches are accompanied by a congestion of the conjunctiva, the treatment of which brings comfort. It is therefore no longer proper to tell the patient seeking relief from headache that glasses alone will cure, simply because there is sufficient error in refraction to cause headache; but rather to explain that the ocular error may be only one factor, and to indicate to him the likely direction toward diagnosis and treatment. He is justified in expecting, in addition to specialism's investigation, medical advice and the inauguration of a medical campaign against his discomfort.

EYE-STRAIN

On the other hand, we know positively that there is a large proportion of headache which is caused by eye-strain alone. G. L. Walton[2] concluded from his statistics that "66 per cent. of patients totally blind from infancy were free from headache." Thirty-one per cent. of seeing patients were free and 29 per cent. with partial or acquired blindness were free. That is, about one half of all headaches are caused by eye-strain. He forever laid to rest the theory that migraine was always to be referred to ocular strain by the assertion that some of the totally blind have migraine, showing that eye-strain cannot be its only cause. Still the alleviation of some cases by glasses indicates that the need of correction of the refraction is sometimes an exciting, or rather, an aggravating, cause.

The headaches caused by ocular errors alone result from a defect in the shape of the eye itself, most frequently manifested by hypermetropia and astigmatism or their combination; from an imbalance of the extrinsic ocular muscles; or from a spasm of accommodation or a strain of the ciliary muscle caused by overuse (frequently during periods of systemic stress as, for example, reading after illness, confinement or a surgical operation).

HYPERMETROPIA AND ASTIGMATISM

The degree of hypermetropia and astigmatism causing headaches is so varying that many high degrees of error cause no discomfort because the patient makes no attempt to obtain clear vision, and therefore there is no great strain on the accommodation, while many low degrees of departure from the normal shape may cause great pain from the effort to see—even more than is normal in certain cases. The American nervous system seems to require a more refined correction even among the lower classes than that of any other nationality. I remember in the clinic of Voelkers at Kiel, a gross error of something like a hypermetropia of three diopters and an astigmatism of equal amount which I had been at great pains to discover. Prof. Voelkers remarked, "Do not bother about the astigmatism. These stupid people cannot make such fine distinctions."

But there are no rules without great and many exceptions in the results of refractive error. A school-teacher came to me in the nineties, complaining of severe headache. One eye converged. When I gave her full correction of a very high hypermetropia, her headache was relieved but her muscle-balance was disturbed in the other direction and the eye diverged, producing a marked deformity. She was nervous and very much displeased until after a reduction in the strength of the glasses and a tonic course of pilocarpin instillations which brought relief from both conditions: but I was never able to prescribe a full correction. I believe that now I should have given her a full correction and then a muscle operation for the deformity later.

IMBALANCE

The question of imbalance of the ocular muscles is complex and the conditions vary so much with the general health of the patient that again one cannot give a definite list of characteristics in the headaches caused therefrom. "In general, frontal headache, perhaps eyeache, combined with slight or great vertigo, nausea, mental confusion, depending on the degree of muscle error and especially in the absence of refractive error, makes one suspicious of insufficiency of an extrinsic muscle which under fatigue may even cause diplopia" (Bull).

A man, aged 31, came to me in 1908 with a history of frontal headaches at times for two years, which had become daily and constant throughout his waking hours for one year, except when he took headache powders. His refractive error was so slight that he was given an addition to his glasses of prisms of 5°+5° bases out for an esophoria. With these he read with ease and his morning headaches disappeared with their use each day. In five days he remarked, "This is the first Sunday in my memory when I could read the entire paper without a headache." He was advised to take regular exercise with an instructor in a gymnasium, the prisms were gradually reduced to 2°+2°, and four years afterward he still worked with comfort without need of a change of glasses.

While actual headache is more infrequent in myopia, it is not too much of a digression to point out that there is a certain mental discomfort connected with the attempt to see, especially in the neurotic myope, which is closely akin to headache. The desire to avoid the appearance of stupidity results in too tense a concentration, which in turn brings on headaches. Another cause of asthenopia, as well as of headache is the half closure of the lids, which results in pressure on the cornea, over the pupil, by the lid margin, which may even cause an actual dent in the epithelium. Bull of Paris demonstrated this occurrence to me after observing it in the eyes of artists who half close their eyes in painting, for the purpose of giving the effect of distance and color values (alinement).

This probably explains some of the discomforts of sitting in the galleries of concert-halls as well as some of the asthenopias with headaches caused by reading in bed. The sequence of events seems to be pressure on the sensitive nerves of the cornea, constantly maintained over the pupil, with reflex spasm of the ciliary muscle, headache and chronic congestion of the conjunctiva.

---

[2] Walton, G. L.: Boston Med. and Surg. Jour., June, 1905.

While the full correction of a patient's refractive error can be obtained only under a cycloplegic, it very frequently happens that one may not force such strong lenses on the patient immediately. The muscle of accommodation, having been accustomed to make a certain effort for a certain piece of work or distance (of focus), seems to resent assistance by glasses and becomes spasmodic instead of relaxing as we hoped it would do. The effort plus the glass makes a blur and the patient must be given a partial correction for a time in order to avoid another vicious circle of blur, spasm and headache.

STRAIN OF CILIARY MUSCLE

There is a well known form of ocular discomfort with headache which is occasionally observed in patients whose eyes are shaped normally and whose extrinsic muscles are properly balanced, yet the use of the eyes in all near work becomes impossible without the greatest discomfort, which may amount to actual pain in the eyes and head. A strain of the ciliary muscle has occurred when the patient was in a weakened general condition. He would not think of using his arm or leg muscles or his back in lifting weights for fear of strain, but he does not hesitate to attempt the muscular act of accommodation when he is too weak to do anything else. Because he is bored to death, he reads everything in sight.

Therefore the ciliary muscle is subjected to an outrageous amount of abuse, and I believe that the most obstinate trouble we have to treat is a strain of the accommodation. Glasses do not relieve and nothing will restore but complete rest, followed by very gradual resumption of exercise. Complete rest may be obtained only by the use of a cycloplegic because every act of seeing may be accompanied by the use of the ciliary muscle. These cases of painful accommodation are sometimes very puzzling and the patients go from one to another ophthalmologist under the belief that if they could only find the correct glasses, they would become comfortable at once.

This question of painful accommodation, with or without an error in the shape of the eye, is one not lightly to be regarded. The patient may be perfectly and indefinitely comfortable in vision for distance, yet cannot read or sew or embroider without pain in the eyes which often extends to neighboring regions. I believe that there are two distinct causes: (1) a strained ciliary muscle described in the preceding paragraph, and (2) reflexes from focal irritations or inflammations, the most frequent of which are nasal. When we have no history of strain preceding either painful accommodation or ciliary spasm, we cannot avoid the thought that many of these cases are reflex. I remember that when Dr. Sluder and Dr. Ewing began their investigation of frontal and ethmoidal headaches, many of the patients complained of great pain in near work. Dr. Andrews of Chicago has recently emphasized the fact of the reflex path from the nasal mucosa by means of sensory fibers to the sphenopalatine ganglion, the interganglion fibers to the ciliary ganglion, from which arise the motor fibers to the ciliary muscle.

"HEADACHE HABIT" AND "HABIT HEADACHE"

The term "headache habit" is used to designate that condition of the nervous system wherein, after the removal of the principal cause, the patient continues to suffer either constantly, yet in diminishing degree, or interruptedly, with the intervals between attacks becoming wider until there is no more trouble. When glasses have been prescribed, the pain does not subside forever and, although the patient may return in a few days highly satisfied with the new conditions, he still later announces that he had a severe attack the day before, often "the worst I have ever had," due, I suppose, to the contrast between the pain of the relapse and the recent freedom from discomfort. The patient and the physician feel that some remedial measure has been left untried.

Dr. Sluder has observed somewhat the same occurrence after the clearing out of a sinus. Congested nerves and poisoned centers do not always respond immediately to treatment even by glasses, and the physician must counsel patience. In this connection also must be mentioned the "habit headache," which means that the person who has been accustomed to suffer at a given time every day or week may have a tendency to returns at such times after correction has been made, especially when the most onerous burdens come at a special time of day in the life of the patient. This type must, of course, be differentiated from the "psychical recurrent morning pains of frontal sinus suppuration, which was once called sun-pain and supposed to be malarial"; and also from the "psychical nocturnal sphenoidal pains," which are self-evidently another entity (Sluder).

VALUE OF THE FIELD OF VISION

The value of the field of vision to the ophthalmologist in cases of headache is rather negative, in that it is used largely to diagnosticate causes from other sources, rhinologic or neurologic. But in these cases it is often of immense value as an indicator. Indeed a neurologic friend goes so far as to say that no headache should be allowed to go without an investigation of the fields, and to a certain extent he is correct, except that if a field were taken in every case of headache which comes to the ophthalmologist, his entire twenty-four hours would be occupied. There is, however, no doubt that when a headache is accompanied by any evidence of optic nerve involvement (an enlargement of the normal blind spot, for example, leads one to suspect sphenoidal or ethmoidal trouble), also when a headache eludes all other diagnostic methods, it is important to go into the subject of the fields more frequently than is usually done. In this connection, I do not believe that a simple field for form or white is of any value whatever in the diagnosis of beginning nerve involvement. In fact, white is not invaded as a rule until the damage is likely to have been done. In nerve inflammations or atrophies, the order of loss is first a narrowing of the green field, followed by a narrowing of the red, blue and yellow, and finally loss of form.

ABSTRACT OF DISCUSSION

Dr. William W. Pearson, Des Moines, Iowa: We can all recall cases like those cited, when we have wondered if it could be possible to find any symptoms anywhere. The doctor has pointed out the cases of weakness and fatigue following long continued illness. So often patients tell us that their headaches followed a major surgical operation, and that they have taken up their eye work at a time when they were absolutely unable to use any other muscles in the body. Surgeons are at fault in not warning patients to refrain from using their eyes during this period. We should all bear in mind that factor of which Dr. Charles spoke with relation to patients whose clear field of vision fails. A few years since a very extensive article appeared in an English journal in regard to the restriction of the field of vision in sinus trouble. It was a good deal along the line of the doctor's paper. One cause that is referred to occasionally in the literature is that of the lid pressure on the globe. I am glad the doctor brought that out. In some individuals who visit the moving picture shows you will notice that their lids are more or less drooped, and you can readily understand how a condition that gives trouble will arise. I am confident that many of these cases are overlooked—headaches resulting from that lid pressure.

Dr. Oscar Wilkinson, Washington, D. C.: One particular form of headache might have been mentioned in connection with Dr. Patrick's paper, but it comes in well with this one. For a number of years I have noticed that basilar headache may be associated with imbalance of the extrinsic ocular muscle, particularly in the exophorias and at times in the hyperphorias. This ocular headache, unlike that spoken of by Dr. Patrick, is not associated with tenderness or with a general infection of the system. It is very frequently, and practically always, associated with the neurotic type of individual with from one to five degrees of exophoria or one to three degrees of hyperphoria. This type of ocular headache is especially associated with neurasthenia. These patients suffer from headache usually the day following severe strain on the eyes; for instance, they wake up in the morning with it. In that respect it must be differentiated from the syphilitic headaches. It is well known that the syphilitic headache is a basilar headache which comes on early in the morning. This headache comes on later than the syphilitic headache and is very often the result of extensive ocular strain.

Dr. Frank Allport, Chicago: This discussion concerns headaches dependent on ocular conditions only. Of course, headaches may arise from other conditions, and I always investigate patients with headaches from all possible angles. If necessary, such patients are referred to general practitioners, neurologists, gynecologists, nose and throat specialists, etc., but I am frequently compelled to limit the cause of the headache to the eye. Headaches are often produced from refractive errors, and especially from astigmatic condition, and more particularly some form of irregular astigmatism. These conditions must, of course, be corrected by glasses, and, when the age of the patient does not prevent, the refractive error should be corrected under the influence of a mydriatic.

Many headaches are produced from instability of the extrinsic ocular muscle, and Dr. Charles advocates the wearing of prisms for such conditions. I do not wish to be understood as saying that prisms should never be worn, but I am convinced that it is a grave error to prescribe them except under very exceptional conditions. A prism is like a crutch—the patient becomes dependent on it, and under its influence the muscle becomes weaker instead of stronger and then stronger prisms must be prescribed. I very much prefer what is known as prism exercise—that is, the exercising or strengthening of certain sets of muscles by prism exercise for a few minutes at a time each day. This almost invariably enhances the power of weak muscles and overcomes the muscular instability and renders the use of prisms in spectacle frames entirely unnecessary.

Dr. Joseph W. Charles, St. Louis: Dr. Pearson spoke of the effect of lid pressure. It is easily explainable. Even one fiber of cotton may cause a lid reflex in testing. The reflex path in these cases of asthenopia caused by lid pressure will be through the long ciliary nerves, through the nasal nerve, through its short root to the ciliary ganglion, the motor fibers from which supply the ciliary muscle. Pressure on the cornea may thus cause spasm of the ciliary muscle. I agree with Dr. Allport in everything he has said about prisms. I think that they have not only been greatly overrated but have done a great deal of damage. The case which I mentioned was an exception. It could not be relieved by any other method; but I do believe in prism exercises.

There is one fact that should be noted in this subject of muscle imbalance. Theobald taught us that a patient may have no imbalance for distance, yet at the reading distance show a decided weakness. He laid down as a general rule that a discrepancy of more than 4 degrees indicated the need of correction or treatment.

TUBERCULOUS EFFUSION, TRAUMATIC IN ORIGIN *

H. A. BRAY, M.D.
RAY BROOK, N. Y.

The case here recorded illustrates the reawakening by trauma of a previous benign tuberculous pleurisy in an apparently healthy person. It also tends to confirm clinically recent experiments on pigs in regard to the pleural reaction in tuberculosis.

REPORT OF CASE

History.—Mrs. L., aged 36, married, housewife, is a large robust woman, weighing 185 pounds. The paternal grandmother, mother and one brother died of pulmonary tuberculosis, and the patient was definitely exposed to this disease for a period of years during childhood. Otherwise the family history is unimportant.

Since the age of 16 she has had repeated attacks of quinsy, and for some years past during the winter months has suffered from recurring attacks of bronchitis.

In 1912, three years previous to the present illness, the patient came to me complaining of pelvic discomfort due to prolapsus uteri. At this time an examination of the chest, suggested by the tuberculous history, revealed a pleuritic patch about the size of the palm of the hand, palpable as well as audible at the base of the right lung posteriorly. Otherwise nothing noteworthy was discovered in the chest. The patient could not recall having had pain or other symptoms referable to this region, and the lesion is of unknown duration. Five subsequent examinations during the next three years, the last, three months previous to the present illness, showed practically no change in the physical signs associated with the pleurisy at the base.

Present Illness.—The onset dates from a wrench of the chest muscles, Aug. 15, 1915, while the patient was in the act of rescuing her small child from drowning. The story of the injury is as follows: Hearing the child's cries for help, she rushed to the stream, stepped from the bank to a projecting rock, and, clutching an overhanging branch with her left hand for support, leaned forward and with the other lifted the child from the water. At this time she felt something within her chest "suddenly give way with a distinct snap," followed by a severe pain at the base of the right lung over the site of the latent pleurisy. It was with considerable difficulty that she returned to the house. The pain grew worse, and that evening she was unable to lie on her right side and was quite short of breath. The pain persisted; she gradually grew weaker, was feverish, and on the tenth day a severe chill sent her to bed. I saw the patient at this time. She was acutely ill, was suffering from severe pain in the chest and had lost considerable in weight. The temperature was 103; pulse, 128; respiration, 32. The physical signs indicated fluid at the base of the right lung extending approximately to the lower angle of the scapula. Otherwise the physical examination was negative. The roentgenograms confirmed the physical findings in all essential details.

The fluid accumulated rapidly, finally occupying the lower two thirds of the chest. Nine hundred and fifty c.c. of clear, straw-colored fluid were removed by paracentesis. Stained specimens showed numerous acid-fast bacilli. Animals inoculated with the fluid developed a typical generalized tuberculosis. The diagnosis, therefore, was tuberculous pleurisy.

---

* From The New York State Hospital for the Treatment of Incipient Pulmonary Tuberculosis.

The patient was ill for about eight months, suffering from a more or less continuous toxemia and losing 40 pounds in weight. The prognosis for a time was distinctly unfavorable. Convalescence then set in. The effusion was absorbed rapidly, and in a few months the patient had fully regained her former state of vigorous health, which has continued to date, a period of approximately two years. The physical examination and roentgenograms one year after recovery failed to reveal evidence of a pleuritic lesion. The fluoroscope showed a slight decrease and retardation in the excursion of the right leaf of the diaphragm.

COMMENT

In apparently healthy persons the development of a tuberculous effusion following trauma of the thorax is usually thus explained: A latent or healed tuberculous focus of the pleura prior to the injury is assumed, except in those instances in which the bacilli gain access to the tissues through an abrasion or wound at the time of the injury. Pathologic studies have demonstrated the frequency of latent foci of the pleura in persons dying of causes other than tuberculosis. It has also been shown that these healed foci may, and often do, harbor living and virulent tubercle bacilli. It is supposed that the trauma causes a rupture of the fibrous capsule about the focus, and that living tubercle bacilli and their products then escape through the tear into the pleural sac. The extent of the effusion and the rapidity with which it develops depend on the number, virulence and distribution of the tubercle bacilli over the pleural surface, and on the allergic state of this tissue.

The clinical data in support of this theory, so far as I have reviewed the literature, is not conclusive. In the recorded cases, the tuberculous focus was not detected prior to the injury, but its presence assumed after detection of the effusion. Furthermore, the time interval between the trauma and the recognition of the effusion in most instances was sufficiently long to admit of the possibility of other causative factors.

These criticisms are not applicable to the present case, since a latent focus of the pleura was recognized several years previous to the injury, and its reawakening by trauma was apparently established from the clinical notes submitted.

At the time of the injury the patient was stooping forward, the left hand raised slightly above the body grasping a limb for support, and the other stretched forward lifting the child (55 pounds in weight) from the water. This effort imposed a severe strain on the muscles of the back, especially those of the right side, and no doubt resulted in the tearing of pleural adhesions, which would account for the sudden and severe pain in the chest. As tubercle bacilli were discovered in the effusion, one may assume that with the tearing of the pleural adhesions, tubercle bacilli were liberated and distributed over a greater or less area of the pleural surface. This was followed by an acute inflammation with rapid accumulation of fluid.

The case, therefore, is of interest in giving added support to our ideas regarding the development in apparently healthy persons of a tuberculous effusion following trauma. It also tends to confirm clinically Paterson's[1] experimental observations as to the possible recovery of the pleura in guinea-pigs from a marked tuberculous involvement. Furthermore, the realization of the untoward results that may follow a wrench of the chest muscles, and the fact that a well established tuberculous effusion does not necessarily mean permanent disability, is important from a medicolegal standpoint. Finally, as tuberculous effusion following trauma is not uncommon, the detection of benign lesions of the pleura should receive careful consideration before accepting men for active military service because of their frequent exposure to injury and the possibility of reactivating lesions of this nature.

OBSERVATIONS ON THREE CASES OF SCURVY

VILHJÁLMUR STEFÁNSSON
NEW YORK

The winter of 1916-1917 was passed in Melville Island by seventeen members of the Canadian Arctic Expedition. The expedition vessel, the *Polar Bear*, had failed to reach the island and we expected to live the winter entirely on fresh or dried musk-ox, reindeer, seal and bear meat. During the darkness of winter, however, our sleds got their steel shoeing worn out through a traveling party getting lost among some rocky hills where the sleds had to be dragged scores of miles, mainly over rock. This necessitated my sending a party in midwinter to Winter Harbor on the same island (where in the past several vessels have wintered) to see if they could find abandoned iron or steel and shoe the sleds for the spring work. Some of our people made another trip to the same place during the winter for a different purpose.

At Winter Harbor our men found, besides the metal and other repair materials wanted, several tons of food, kerosene, etc., cached there in 1910 by Captain Bernier, then in the Canadian government service. It was against my judgment, because of fear of scurvy and because of trouble in freighting the food, to use any considerable quantity of these edibles at our winter camp; but the men had an idea that the cached foods were much preferable to meat, and so I allowed them to eat all they wanted of these groceries while at Winter Harbor, though the amount hauled to the base camp and eaten there was less than three full meals per week—one full meal per week would be nearer the actual fact.

The main items of food found at Winter Harbor were flour, salt pork, butter, honey, sugar, pilot bread, preserved fruit in glass containers, pemmican, meat extract, dried fruit, rice, beans and peas. So far as we could judge, all of this food was in perfect condition except the pork and the sugar. Much of the brine had leaked out of the pork barrels, and as they were above the sugar, some of the brine had permeated most of the sugar so that the taste of it ranged from barely perceptible saltiness when used in tea to saltiness that made the sugar disagreeable no matter how used. There may have been a little sugar unaffected. The pemmican was salted to be palatable to the ordinary eater; the meat extract seemed to consist in considerable part of rock salt, some of the particles nearly the size of a split pea. There was also some salt which those of the men who cared for it used with the fresh meat.

On account of their greater portability, I decided to use the groceries found at Winter Harbor along with dried meat and fat on the sledge exploration of the spring of 1917. The dried meat yields to no food in portability if used with the right amount of tallow, but as we had to feed some fifty dogs on it as well as the men we were short and should have had to use half dried or green meat in part had we not found the cached groceries. I did not fear scurvy from this use of the groceries, as I expected the men to eat mainly fresh meat all winter and we would have some seal meat on the ice in the spring. But I reckoned without the fact that some of our men had the belief that a varied diet is necessary for health. That phrase may be all right if properly understood; but certainly it is not only untrue as commonly understood by laymen but dangerous when applied on polar expeditions by the ordinary cook or even by that type of doctors who inherit their views of scurvy and antiscorbutics from Captain Cook's voyages. On this point witness the prevalent scurvy of the carefully groomed, dieted and medically supervised Scott expeditions and the absence of it on the (dietetically) apparently haphazard expeditions of Peary and Shackleton.

---

[1] Paterson, R. C.: Pleural Reaction to Inoculation with Tubercle Bacilli in Vaccinated and Normal Guinea-Pigs, Am. Rev. Tuberc., 1917, 1, 353.

Of the five men who went to Winter Harbor in midwinter and there lived for several weeks mainly on the diet given above (the cached stores), three were afterward transferred to parties that lived in considerable part on fresh meat through February and March, and none of them ever contracted scurvy. The other two worked at freighting the groceries to the north coast of Melville Island and (I later learned) ate fresh meat rarely and as only one item of their meals. They also used salt extensively both as direct seasoning and in the form of beef tea from the meat extract. Both these got scurvy late in March or in April. No one else of the seventeen in Melville Island had any symptom of scurvy.

In March, our Melville Island party was joined by Lorne Knight, who had wintered with the *Polar Bear* in Victoria Island and whose diet had been mainly groceries of the ordinary kind, with a little fresh meat now and then, cooked in the ordinary white man's way.

After Knight joined our party, it was subdivided into two sections traveling one behind the other on the same trail, a few days apart. In the advance party were Aarnout Castel (in command), Karl Andersen, Lorne Knight, Harold Noice and one Eskimo; I learned later that the diet of this party had been mainly rice, pilot bread, pemmican, meat extract, sugar (salty), honey and a little fresh meat, cooked. The Eskimo, in addition, occasionally ate some raw fresh meat kept for dog feed. Castel ate the salty, cooked food, but he had previous to taking command of this party lived nearly exclusively on meat all winter, some of it eaten raw and little salt used. He and the Eskimo never acquired scurvy. The second party, that traveled behind, had a diet differing from the first in less use of salt and more of meat, both cooked and raw. No one in that section developed scurvy at any time.

Early in April, Andersen, when my party caught up to the advanced section, complained to me of having been gradually becoming more unwell for a week or two. The first symptom noted by him was dizziness on suddenly standing up, "laziness," gloom and irritability, showing itself in a tendency to condemnatory and uncalled for argumentativeness, proneness to becoming tired, and loosening of the teeth and a swelling and recession of the gums, with a dull, local ache in the gums or roots of the teeth. The appetite was normal as to both quantity and kind of food desired except that there was an increased aversion to frozen, raw meat—occasionally eaten by most of us in the form especially of frozen liver, a dish few persons can try several times without acquiring a liking. I told Andersen at once that the case looked like scurvy to me, but I added, "It can't be, for you have lived on fresh meat most of the winter." To this he replied, "No, sir, it can't be"—a dutiful reply, but not enlightening. So I decided the gum condition to be pyorrhea alveolaris, and we acted accordingly. I sent Andersen south with the first returning support party going toward our base at Cape Kellett, Banks Island.

I learned later that on the way south Andersen's symptoms continued to develop along the same lines, and he lost gradually in strength. On reaching Melville Island, the party failed to find food at an expected rendezvous, and for two or three days they had been on short rations, arriving without food at a place where several musk-oxen had been killed and one left behind unskinned and intended for dog feed. The coat of this animal is so warm that in the coldest weather of winter, decay for several days proceeds on the basis of the body heat before being arrested by frost. This animal was therefore very "rotten," but the party was hungry and promptly devoured considerable of the frozen meat. All men who know the two methods prefer very high meat raw and frozen to the same meat cooked, and so our party ate most of their food raw for some days. Andersen told me the following summer that after three days of the raw meat he was completely over his abnormal gloom, felt eager to exert himself (as exemplified by a willingness to get up in the mornings, whereas he had formerly to "drag himself out of bed"), he could stand up suddenly without dizziness; and a soreness and stiffness of the joints, lately a prominent symptom, had disappeared. All this had occurred in three days. On a continued diet of meat, sometimes raw, sometimes cooked, but always fresh after the first four or five days, he continued to improve. His full strength came back in two weeks and his gums were firm and his teeth fast in a month. No salt was used, for they had run out of it.

In complete ignorance of the progress of Andersen's disease and of his recovery, my own party proceeded out on the moving sea ice and to a point 140 miles from land. Here scurvy, this time promptly recognized, laid hold of two of my three companions, Knight and Noice. What helped me to a quick decision as to what the trouble was was Noice's telling me that at times, when they were working separated from me, they had eaten practically no fresh meat for a considerable part of the winter, and had been eating everything heavily salted, partly (apparently) as a protest against what they considered my unreasonable instructions that meat should be the main item of diet and salt used sparingly, though both "white men's food" and salt had been found at Winter Harbor.

Noice, who had been on the Winter Harbor diet, and Knight, who had been on the ship's diet, had about the same symptoms, and these were the same as in Andersen's case. Noice's disease, however, was about a week farther advanced than Knight's. We at once started for land, for seals were scarce where we were, and fresh meat not available. I ceased using any salt or salty food, and for the first week of the journey shoreward the symptoms remained about at a standstill. After that, however, the disease made progress again. The diet at this time was hard bread, rice, pea meal, honey, sugar and casein. What fat we had we used for the dogs.

Before reaching shore, Noice had become unable to walk and had to be hauled on the sleds; Knight was able to walk, but was getting weaker and more wretched. On landing on Ellef Ringnes Island, I at once went inland in search of caribou, the others traveling along the coast to keep abreast of me. On the second day, fourteen caribou were killed, and we pitched camp at the place.

At this time the teeth of both men were so loose that they could be plucked out with the fingers with no effort, and the gums were of such a cheeselike consistency that they were cut (with little bleeding) by wooden toothpicks about as easily as ordinary "American" cheese could be. Every joint was sore and all movements painful, and there was a gloom which, both men later agreed, could not have been caused by mere worry over their danger—we were 700 miles from our vessels and 600 from the nearest Eskimos. There was a marked craving for salt, in consequence of which I threw away a pound of salt we had with us and a little remaining meat extract, to prevent the men eating them surreptitiously. Appetite and digestion seemed normal, except that there were the abovementioned craving for salt and a pronounced distaste for raw meat—greater distaste than ordinarily. I now put them on this diet: In the morning a potful of meat was boiled, without salt, in enough water to supply drinking needs all day. The boiled meat was all consumed at breakfast, and when they were hungry enough (which was soon), raw frozen meat was eaten as often as desired the rest of the day. This meant that from half to two thirds of the meat was eaten raw. Marrow was also eaten raw.

In three days of this diet both men felt as cheerful as normal, and instead of the previous disinclination to stir there was a desire for activity surprising in view of the weakness from which they had not yet recovered. The pain in the joints was nearly gone, the craving for salt was markedly less, and the appetite for raw meat was much improved. In fourteen days from the first meal of meat, both men were able to walk, and we started south. In another two weeks their teeth were secure and the gums hard, though they did not, of course, regain their former apposition or contours.

All these men have been traveling all winter, having exercise that amounted to hard work, and fresh air night and day. None of them took a bath shortly before, during or immediately after their illness.

I have found among medical practitioners in Alaska that, with the prejudice in favor of fruit and vegetables as antiscorbutics inherited from Captain Cook's interesting observations, they have neglected meat as a preventive and curative agent in general throughout the territory. This led to many uncalled-for deaths while vegetables were as yet not readily obtainable. Fresh meat and fish always have been readily obtainable in most places.

Apart from some cases of scurvy that I dealt with in an article published last May,[1] I have seen in addition to the foregoing case only my own. I knew in advance I was likely to get scurvy during the winter of 1917-1918 if I continued on the diet forced on me by local conditions in the Mackenzie delta, where I was buying dogs, but I intended to counteract this by a prompt change to a meat or fish diet as soon as that task was done. But just then I was taken with typhoid, followed by pneumonia and pleurisy; and the diet approved and forced on me by those under whose charge I was while extremely ill was one by no means calculated to counteract scurvy—ordinary canned milk. But as this case, both in its cause and cure, differs markedly from the foregoing, I shall decide that space does not warrant my including a full account of it here.

CONCLUSIONS

The present article, together with the one just mentioned, and considerable material gathered but not published, makes clear some conclusions and suggests others. While these may not be exactly new, it is to be judged by the confused nature of many medical works still in use for reference by physicians that further testimony would not be amiss.

It seems, then, that:

1. The strongest antiscorbutic qualities reside in certain fresh foods and diminish or disappear with storage by any of the common methods of preservation—canning, pickling, drying, etc. Fresh tomatoes may be valuable (I have never tried them), but canned tomatoes are of little or no value; fresh potatoes are good, but desiccated potatoes have shown little or no adequacy in our expedition when tried in my absence by believers in that form of diet; the juice just expressed from the fresh lime is said to be excellent, and I have no reason to doubt it; but bottled lime juice has never yet prevented scurvy. (I have just recently gathered interesting but scarcely needed testimony on this point from the Royal N. W. Mounted Police as to the scurvy winter of 1898-1899 at Dawson).

2. Cooking lessens or destroys the antiscorbutic value of most or all foods. Three average raw potatoes are commonly said by miners definitely to turn the tide of scurvy that has not reached an extreme stage; in our own expedition, boiled and roasted fresh bear meat did not relieve scurvy except with such slowness that it is debatable just what its effect was, if any. Our party and persons known to me have had the same experience with venison. I am of the opinion that most men, if left to their own inclinations and supplied with abundant cooked, fresh meat will avoid scurvy; cooked meat acts but slowly on an advanced case—the efficiency of it depending probably on the "rareness" of the cooked meat.

3. Meat and fish slightly or well advanced in the process of ordinary putrefaction seems to be as good an antiscorbutic as fresh flesh, or nearly so—witness Andersen's case above and the well-known fact that Eskimo tribes often live for several months in succession on putrid meat or fish without ever developing scurvy, while Eskimos working for white men or living on purchased provisions have it quite as readily as Europeans living on the same sort of diet.

4. Bodily cleanliness and ventilation are not by any facts known to me shown to have any bearing on the incidence or severity of scurvy. Here it is instructive to compare the filth and good health of Nansen and Johansen, as described in "Farthest North," with the

---

[1] Stefánsson, Villhjálmur: Original Observations on Scurvy and My Opinion of the Medical Profession, Med. Rev. of Rev., 1918, 24, 257.

immaculate Scott expeditions with their numerous and serious scurvy cases.

5. Exercise does not prevent scurvy. I have been told, verbally, that the Scott party had it on the return from the pole, after months of continuous and strenuous work in the purest of pure air and in abundant, continuous sunshine; while Nansen and Johansen were in perfect health after a winter of the most nearly absolute inactivity ever known to me to have been described in a book of travel. These are not isolated but typical instances.

6. Salt, while not proved by anything I know to be a cause of scurvy, probably has some direct bearing on the history of the disease, for the following reasons: (*a*) Salt meats have long been recognized (and probably rightly) as predisposing to scurvy. (*b*) Many observers have commented on the hankering for salt by scurvy patients and on the disappearance of the longing as the cure proceeds.

Neither am I certain that salt did not cooperate with the heat in lessening the antiscorbutic value of the meat used by four of our eight scurvy patients. The only death and the only long and dragging recoveries were of men who ate their meat cooked and salted during or after cooking. This was at the winter camps which, while they belonged to our expedition, were not at the time under my personal observance, and I have the stories on hearsay.

7. It is a mistake to think (with most laymen and many physicians) that blackening the skin of the leg and softening of the calf muscles are among the early symptoms in nearly all cases. I have never seen either symptom, and in the cases I have heard of from reliable observers these symptoms, if they appeared, appeared late in the disease. Dizziness on standing up and bleeding from the gums are commonly among the earliest symptoms noted by the sick man himself, though it may be right that careful tests would disclose other symptoms earlier.

Harvard Club.

Birth Statistics.—According to an advance report of the Bureau of the Census, during the year 1916 in the recently established birth-registration area of the United States, with an estimated population of about 33,000,000, or 32 per cent. of the total population, the birth rate was 24.8 per thousand of population. This area comprises the six New England States, New York, Pennsylvania, Maryland, Michigan, Minnesota and the District of Columbia. The number of infants born alive was 818,893. The total number of deaths in the same area during the same period was 486,482, or 14.7 per thousand. The births, therefore, exceeded the deaths by 68 per cent. It is said that in all the states and all the cities, and in practically all the counties of the birth-registration area, the births exceeded the deaths, usually by considerable numbers. The deaths of infants of less than 1 year averaged 101 per thousand of living births. The birth rate for the entire registration area fell below that for 1915 by 0.1 per thousand of population, while the death rate exceeded that for 1915 by 0.7 per thousand. Without migration and with the birth and death rates remaining constant in the area to which they relate, the annual increase in population would be about 1 per cent. This rate compounded for a decade would give a decennial increase of about 10 per cent., or about half the rate of increase in the population as a whole between the last two censuses, which was 21 per cent. More births occurred to foreign-born white women than to native white women, amounting to as much as 62 per cent. in Connecticut. The death rate among infants of less than 1 year was practically the same in 1916 as in 1915—101 to 100 in the latter year. It ranged from 70 in Minnesota to 121 in Maryland.

PARALYSIS OF THE SIXTH CRANIAL NERVE ASSOCIATED WITH OTITIS MEDIA *

JOHN M. WHEELER, M.D.
NEW YORK

In the routine practice of ophthalmology when patients present themselves with extra-ocular muscle paralyses which have developed suddenly, one is inclined to be content with inferring probable syphilitic etiology or some toxic cause, in case there is no history of traumatism. This habit of practice has led too often to the neglect of a careful search for a definite underlying cause and a definite pathologic lesion.

There are many conditions that may be responsible for paralysis or paresis of the third, fourth and sixth cranial nerves, and the whole subject is full of interest; but I wish at this time to call attention definitely to paralyses of a single nerve, namely, the abducens, which occur rarely but unmistakably in the course of purulent otitis media.

In 1904, Gradenigo[1] described a symptom complex which is now known as Gradenigo's syndrome or triad. It is characterized by (*a*) acute otitis media (with or without external suppuration, and with or without mastoid reaction); (*b*) isolated paralysis or paresis of the abducens nerve of the side corresponding to the diseased ear, and (*c*) intense and extraordinarily persistent pain localized, not as ordinarily in the mastoid region, but in the frontal, temporal and parietal regions of the same side.

The following case is a clean-cut example of the type:

M. W. S., aged 11, a thin and rapidly growing girl, called at my office, June 9, 1917. Two years before she had been a victim of mastoiditis on the left side and the mastoid was successfully operated on by Dr. John D. Richards. For the last six weeks she had had a running ear on the right side and was being treated conservatively by Dr. Philip D. Kerrison. The child was brought to me on account of double vision, which she overcame by closing the right eye, and very severe pain in the right side of the head, which was most intense over the right eye. Examination revealed complete paralysis of the right external rectus. Gradenigo's syndrome was clearly exemplified, and the condition was reported to Dr. Kerrison, who thought best to perform the mastoid operation. Two days after the patient visited me, the mastoid was cleaned out and it was found to be of the pneumatic type; but nothing unusual was found in spite of careful search for a lead to the sixth cranial nerve. The next day after operation there was decided improvement in the diplopia, and on the third day the diplopia and the pain had entirely disappeared, not to return again. I saw this patient last, Dec. 8, 1917, and at that time the muscles were in balance, and the tropometer showed normal rotations.

Recognition of the symptom group is found in otologic literature by the detailed reports of numerous cases which adhere more or less closely to the definite Gradenigo type; but case reports in eye literature are few, and there is surprisingly inadequate reference to the association of isolated sixth nerve paralysis with otitis in our textbooks and journals, and one is led to believe that the importance of this association has been rather generally overlooked by ophthalmologists. Knapp,[2] in 1908, reported a well-defined case:

---

* Read before the Section on Ophthalmology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Gradenigo: Tr. Cong. de Bordeaux, 1904.

E. B., girl, aged 5 years, a well developed and previously healthy child, after an attack of grip, suffered from headaches and pain in the right ear. This persisted for two weeks and was associated with unusually severe pain in the right half of the face and in the right eye. The gums on the right side of the mouth were so sore that she could not chew. The mother then noticed that the right eye turned in.

Feb. 29, 1908, the right eye was in a convergent position. There was no outward motility beyond the middle line. There was homonymous diplopia. Vision was normal. Sensibility was unchanged. There was no history nor sign of herpes. The field was normal. The right eardrum was red, verging to white, was slightly bulging, and there was no perforation. As there was no pain and the ear condition was on the way to recovery, no paracentesis was done. The child was kept quiet; a hot-water bag and calomel in small doses were prescribed.

March 17, the general condition was much better. The eardrum was nearly normal. The ocular paralysis was unchanged.

March 25, the right eye could be turned outward 20 degrees.

April 8, there was motility not quite to the external canthus; there was homonymous diplopia.

May 14, motility was normal. There was no diplopia. There was an intercurrent attack of headache and earache, but no return of the ocular paralysis.

June 11, the patient was well.

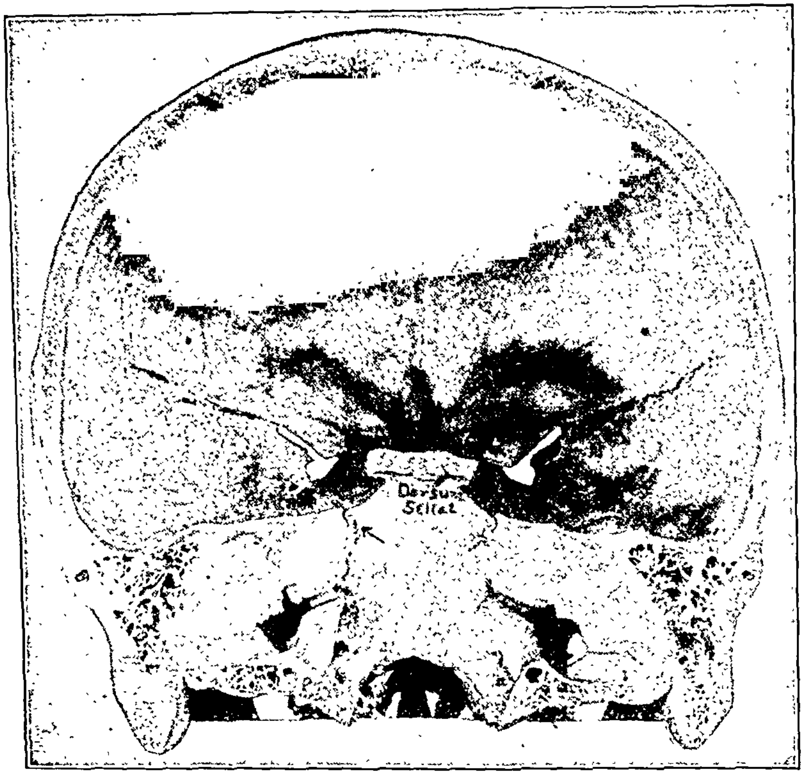

Fig. 1.—Vertical section through skull, posterior view. Arrows point to grooves at apexes of petrous portions of temporal bones, in which the sixth cranial nerves lie.

Other cases reported in eye literature are those of Terson,[3] Peyser,[4] Sauvineau,[5] Koellner,[6] Goetermann[7] and Myers.[8]

In 1908, L. Baldenweck,[9] intern on the ear service of the Lariboisiere Hospital, published a comprehensive essay on the alterations of the gasserian ganglion and paralysis of the sixth nerve in the course of inflammation of the middle ear, with case reports.

In 1910, Perkins[10] reported three cases that had been under his care for mastoiditis with paralysis of the sixth nerve, reports two cases from the practice of Dr. Alfred Wiener, and one that had been treated by Dr. S. J. Kopetsky. He covers the whole subject in an admirable way from the standpoint of the otologist, and gives a comprehensive bibliography.

Rarely paralysis of the sixth nerve is associated with external otitis. For this reason it may be of interest to report the following case:

Feb. 5, 1918, T. L., man, aged 24, came to the eye clinic at the New York Eye and Ear Infirmary complaining of double vision and turning in of the left eye of one day's duration, and pain in the left auricular region. Ten days before he had injured the canal of his left ear with a hairpin, and furunculosis of the canal had developed. The furuncles had been incised five days before. Considerable edema of the canal remained, and there was almost complete paralysis of the left external rectus without involvement of the third, fourth, fifth, seventh or eighth cranial nerves. Examination revealed no evidence of middle ear inflammation. There was, however, mild retinitis of both eyes, with recent hemorrhages and markings which indicated old hemorrhages or exudates. The Wassermann and Noguchi tests of the blood were negative, but the urinalysis showed evidence of an old gonorrheal infection of the urethra. February 9, five days after the patient began to see double, he returned to the eye clinic with orthophoria in the primary position and binocular single vision in all fields. The swelling in the external auditory canal and the pain had disappeared.

In this case it is possible, but not likely, that the sixth nerve paralysis was due to gonorrhea, or that some other constitutional condition was responsible for both the retinitis and the abducens paralysis. Even in such a case as this a transient edema, dependent on the furunculosis and involving the periosteum and fascial tissues at the apex of the petrous pyramid, may affect the sixth nerve in this position. This is the sort of case, however, to which the reflex theory of abducens paralysis best applies. This theory has been largely abandoned as unnecessary and somewhat fanciful.

The ocular paralysis is always seated in the external rectus of the side corresponding to the otitis. However, in a case reported by Rimini,[11] there were double otitis media and double external rectus paralysis. In another case, which I recently observed, there was one-sided mastoiditis with paralysis of both external rectus muscles.

C. T., girl, aged 10, Italian, was admitted to St. Mary's Free Hospital for Children, Feb. 12, 1918, with a history of purulent discharge from the left ear for four weeks, and deviation of the left eye for two weeks. The left mastoid had ruptured and pus had invaded the muscles of the neck. The day after admission, February 13, Dr. Edward D. Truesdell performed a mastoid operation. At the request of Dr. Colman W. Cutler, the consulting oculist to the hospital, I examined the patient, March 9, at which time Dr. Truesdell reported satisfactory improvement as a result of the mastoid immaculate Scott expeditions with their numerous and serious scurvy cases.

5. Exercise does not prevent scurvy. I have been told, verbally, that the Scott party had it on the return from the pole, after months of continuous and strenuous work in the purest of pure air and in abundant, continuous sunshine; while Nansen and Johansen were in perfect health after a winter of the most nearly absolute inactivity ever known to me to have been described in a book of travel. These are not isolated but typical instances.

6. Salt, while not proved by anything I know to be a cause of scurvy, probably has some direct bearing on the history of the disease, for the following reasons: (*a*) Salt meats have long been recognized (and probably rightly) as predisposing to scurvy. (*b*) Many observers have commented on the hankering for salt by scurvy patients and on the disappearance of the longing as the cure proceeds.

Neither am I certain that salt did not cooperate with the heat in lessening the antiscorbutic value of the meat used by four of our eight scurvy patients. The only death and the only long and dragging recoveries were of men who ate their meat cooked and salted during or after cooking. This was at the winter camps which, while they belonged to our expedition, were not at the time under my personal observance, and I have the stories on hearsay.

7. It is a mistake to think (with most laymen and many physicians) that blackening the skin of the leg and softening of the calf muscles are among the early symptoms in nearly all cases. I have never seen either symptom, and in the cases I have heard of from reliable observers these symptoms, if they appeared, appeared late in the disease. Dizziness on standing up and bleeding from the gums are commonly among the earliest symptoms noted by the sick man himself, though it may be right that careful tests would disclose other symptoms earlier.

Harvard Club.

Birth Statistics.—According to an advance report of the Bureau of the Census, during the year 1916 in the recently established birth-registration area of the United States, with an estimated population of about 33,000,000, or 32 per cent. of the total population, the birth rate was 24.8 per thousand of population. This area comprises the six New England States, New York, Pennsylvania, Maryland, Michigan, Minnesota and the District of Columbia. The number of infants born alive was 818,893. The total number of deaths in the same area during the same period was 486,482, or 14.7 per thousand. The births, therefore, exceeded the deaths by 68 per cent. It is said that in all the states and all the cities, and in practically all the counties of the birth-registration area, the births exceeded the deaths, usually by considerable numbers. The deaths of infants of less than 1 year averaged 101 per thousand of living births. The birth rate for the entire registration area fell below that for 1915 by 0.1 per thousand of population, while the death rate exceeded that for 1915 by 0.7 per thousand. Without migration and with the birth and death rates remaining constant in the area to which they relate, the annual increase in population would be about 1 per cent. This rate compounded for a decade would give a decennial increase of about 10 per cent., or about half the rate of increase in the population as a whole between the last two censuses, which was 21 per cent. More births occurred to foreign-born white women than to native white women, amounting to as much as 62 per cent. in Connecticut. The death rate among infants of less than 1 year was practically the same in 1916 as in 1915—101 to 100 in the latter year. It ranged from 70 in Minnesota to 121 in Maryland.

PARALYSIS OF THE SIXTH CRANIAL NERVE ASSOCIATED WITH OTITIS MEDIA *

JOHN M. WHEELER, M.D.
NEW YORK

In the routine practice of ophthalmology when patients present themselves with extra-ocular muscle paralyses which have developed suddenly, one is inclined to be content with inferring probable syphilitic etiology or some toxic cause, in case there is no history of traumatism. This habit of practice has led too often to the neglect of a careful search for a definite underlying cause and a definite pathologic lesion.

There are many conditions that may be responsible for paralysis or paresis of the third, fourth and sixth cranial nerves, and the whole subject is full of interest; but I wish at this time to call attention definitely to paralyses of a single nerve, namely, the abducens, which occur rarely but unmistakably in the course of purulent otitis media.

In 1904, Gradenigo[1] described a symptom complex which is now known as Gradenigo's syndrome or triad. It is characterized by (*a*) acute otitis media (with or without external suppuration, and with or without mastoid reaction); (*b*) isolated paralysis or paresis of the abducens nerve of the side corresponding to the diseased ear, and (*c*) intense and extraordinarily persistent pain localized, not as ordinarily in the mastoid region, but in the frontal, temporal and parietal regions of the same side.

The following case is a clean-cut example of the type:

M. W. S., aged 11, a thin and rapidly growing girl, called at my office, June 9, 1917. Two years before she had been a victim of mastoiditis on the left side and the mastoid was successfully operated on by Dr. John D. Richards. For the last six weeks she had had a running ear on the right side and was being treated conservatively by Dr. Philip D. Kerrison. The child was brought to me on account of double vision, which she overcame by closing the right eye, and very severe pain in the right side of the head, which was most intense over the right eye. Examination revealed complete paralysis of the right external rectus. Gradenigo's syndrome was clearly exemplified, and the condition was reported to Dr. Kerrison, who thought best to perform the mastoid operation. Two days after the patient visited me, the mastoid was cleaned out and it was found to be of the pneumatic type; but nothing unusual was found in spite of careful search for a lead to the sixth cranial nerve. The next day after operation there was decided improvement in the diplopia, and on the third day the diplopia and the pain had entirely disappeared, not to return again. I saw this patient last, Dec. 8, 1917, and at that time the muscles were in balance, and the tropometer showed normal rotations.

Recognition of the symptom group is found in otologic literature by the detailed reports of numerous cases which adhere more or less closely to the definite Gradenigo type; but case reports in eye literature are few, and there is surprisingly inadequate reference to the association of isolated sixth nerve paralysis with otitis in our textbooks and journals, and one is led to believe that the importance of this association has been in the same degree as the cavernous and the inferior petrosal, because it does not follow the superior border of the petrous pyramid to its apex, but curves forward to join the cavernous several millimeters anterior to the petrous apex.

---

* Read before the Section on Ophthalmology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Gradenigo: Tr. Cong. de Bordeaux, 1904.

The small area of contact of the abducens with the petrous bone at or near its tip is marked by a little groove, and just external to and behind the groove is a little spicule of bone; and on the border of the dorsum sellae of the sphenoid is another spicule. Between these two spicules of bone, and stretching closely over the sixth nerve, is a firm ligament, which sometimes undergoes partial or complete ossification, and to this ligament is attached the dura mater and fascial connective tissue layer, referred to above, which the abducens penetrates. Thus it will be seen that right at this point the anatomic arrangement is such that exudate or hemorrhage from an inflammatory process or from traumatism, or edema from any cause, would be likely to interfere with the function of the abducens by pressure or strangulation.

In order to understand the severe pain that occurs on the corresponding side of the head in these cases, it is important to have in mind the close proximity of the gasserian ganglion to the tip of the petrous bone. It lies in Meckel's dural cavity and rests in a depression on the anterosuperior aspect of the petrous pyramid at its tip, so that a process which would affect the sixth nerve at the tip would be likely also to affect the gasserian ganglion.

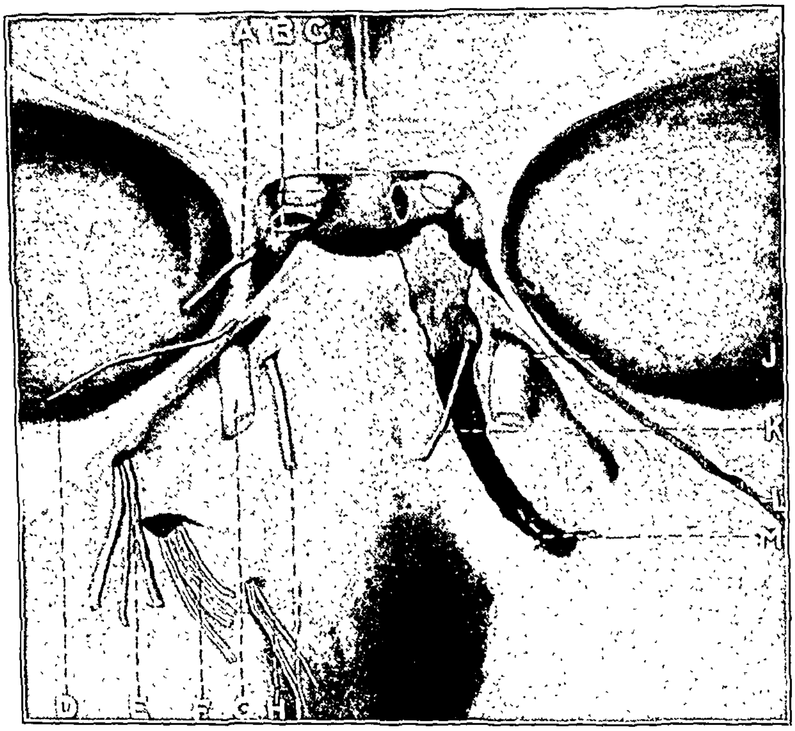

Fig. 3.—Drawing from wet specimen. The brain has been removed. On left side cranial nerves are seen entering dural openings. On right side dura has been removed to show sixth nerve entering connective tissue in posterior wall of cavernous sinus, a little below and behind apex of petrous pyramid. *A*, third nerve; *B*, carotid artery; *C*, second cranial (optic) nerve; *D*, fourth nerve; *E*, seventh and eighth nerves; *F*, ninth, tenth and eleventh nerves; *G*, fifth nerve; *H*, twelfth nerve; *I*, sixth nerve; *J*, fifth nerve entering Meckel's cavity for gasserian ganglion; *K*, sixth nerve entering connective tissue; dura has been removed; *L*, superior petrosal sinus; *M*, inferior petrosal sinus.

In ordinary otitis media it is entirely possible for the inflammatory process to extend to the apex of the petrous bone and to produce an edema or a local toxemia which will cripple the function of the sixth nerve at the vulnerable point in which we are especially interested in this study. Occasionally the petrous bone is strikingly pneumatic, and it is in such a bone that the purulent process would be most likely to invade the pyramid to the apex. Figure 2 illustrates a petrous bone of pneumatic character with a large cell directly under the groove for the lodgment of the sixth nerve, and is very convincing in this connection.

In order to reach a cell at the petrous tip there are many possible routes of invasion for infection. Perkins[15] mentions the following: (*a*) The infection may follow the sublabyrinthine route extending from the tympanum below the labyrinth and internal auditory meatus to the petrous tip. An interesting case in which the infection traveled this path is reported by Lombard.[16] Death occurred from meningitis. Necropsy revealed pus in the tip cells with very pneumatic bone. On the healthy side, the cells in the petrous tips were very large, and mercury poured into them emerged in the middle ear. (*b*) From the mastoid antrum the infection may extend through the subarcuate fossa or petromastoid canal, which passes inward beneath the superior semicircular canal, and reach a layer of cells sometimes lying above the internal auditory meatus and thus arrive at the petrous tip, (*c*) or this point may be arrived at by way of the carotid canal, access to which is obtained either by eroding the bone on the anterior tympanic wall, or through one of the caroticotympanic foramina which give passage to the carotid branches of the tympanic plexus, or (*d*) finally the infection has been found in some necropsies to be through a layer of cells extending along the eustachian tube, thus passing from the tympanum to the petrous tip.

In some cases of mastoiditis, paralysis of the external rectus of the corresponding side has been observed after the mastoid operation has been performed. In some of such cases probably the chief causative factor has been traumatism attending the operation itself, and one would expect this to take place most often in cases in which ebony hard bone has necessitated the vigorous use of the mallet. It is not difficult to see how this might disturb the tissues at the apex of the petrous pyramid in such a way as to produce hemorrhage or edema that would result in pressure paralysis of the sixth nerve at this vulnerable point.

PROGNOSIS AND TREATMENT

The paralysis may clear up in a few days, and in a few cases has disappeared almost miraculously after mastoid operation, as in Perkins' second case and in my first case. But usually it persists for weeks or months, and there is possibility of permanent impairment of the nerve.

The treatment lies in the field of the otologist, and should be left to him, for recovery from the abducens paralysis depends on his success in treating the ear condition. Although Gradenigo's syndrome may indicate a deep-seated process, this in itself does not justify mastoid operation in every case, for recovery has occurred in a number of cases without mastoid operation and even without myringotomy.

ABSTRACT OF DISCUSSION

Dr. Walter H. Snyder, Toledo, Ohio: I have seen only one case of the condition described by the essayist. This was in a young woman who had had an acute otitis media, complicated by mastoiditis. She had been unconscious for about a week, or, at least, was in a deep stupor, when I first saw her. The day after her admission to the hospital she was operated on and died three days later without regaining full consciousness. The last day it was noted that she had a paralysis of the abducens on the side of the diseased mastoid. In this case the trauma of the operation did not cause the paralysis, as the tissues were very soft, no eburnation of the diseased bone had taken place, and it was easily removed with the hand curet, chiseling not being necessary. It is even possible that the operation did not go far enough, but the condition of the patient precluded any further investigation. We explored the tip especially and felt we had good drainage and that there was no necessity to enter the brain cavity, as apparently every part was draining and clean. Considering the anatomic relations, it is not surprising that this condition occurs; in fact, we would expect to find it much more common than it is, especially where the mastoid involvement has penetrated the inner table of the skull. It is, however, a comparatively rare condition. It is probable that many of the severe cases of mastoiditis exhibit this complication late in the disease, when the patient is moribund or lying with the eyes closed, hence is not noticed. The frequency with which this nerve is affected in basilar inflammations, especially in the syphilitic infections, would lead one to think that this complication would be more common in this rapidly spreading and especially destructive type of mastoid inflammation caused by *Streptococcus capsulatus,* of which the case I mention was an example.

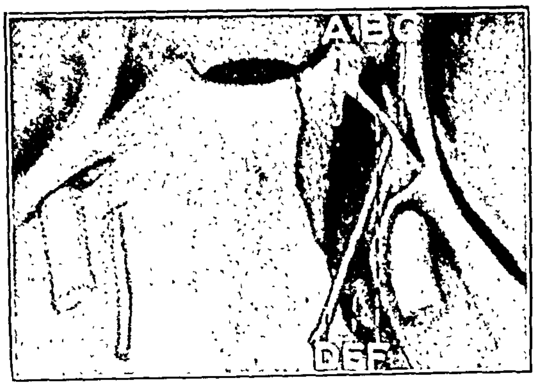

Fig. 4.—Further dissection to show sixth nerve entering cavernous sinus in relation to external wall of inferior petrosal sinus and in contact with apex of petrous pyramid. *A,* posterior clinoid process; *B,* carotid artery; *C,* apex of petrous pyramid; *D,* sixth nerve; *E,* inferior petrosal sinus; *F,* ligament.

Dr. H. H. Stark, El Paso, Texas: I recently had a similar case in a child 4 years old. The case was in the care of a general practitioner for at least three weeks after the primary attack of sore throat, which was followed in three weeks by a discharge from the right ear. In describing the case to me the physician said that it might have been scarlet fever; that he was unable to make a diagnosis. On coming to me the child had the syndrome described, pain with paralysis of the externus on the right side, the side on which the ear was involved. The ear was discharging freely, and a roentgenogram showed involvement of the cells. The temperature at the time was 102 F. The patient was placed in the hospital, and the fever subsided in two days. The discharge continued for two weeks and then stopped. No operative procedure was done. Complete recovery occurred within two weeks after the discharge had ceased. At the time the bacteriologic examination showed a streptococcus infection. I felt that the paralysis was one of toxemia, as we had had during this period of about six weeks several cases of infection of the same character, in which paralysis of the facial nerve occurred. One patient, a young man of 35, had a temporary hemiplegia lasting two weeks. I do not doubt Dr. Wheeler's deduction in these cases. I believe that they are due to a direct involvement of the sixth nerve from the misplaced cells.

Dr. John M. Wheeler, New York: If we will be on the lookout for this syndrome, we will find that this is not a rare condition. The prognosis is, on the whole, good. In some of these cases the paralysis is entirely cleared up a few days after operation; in some cases, within a few weeks or months; in some cases without operation, and in only a very few cases has the paralysis been permanent. The treatment lies entirely within the field of the ear surgeon, and the prognosis depends a great deal on his success in draining the mastoid cells.

ACQUIRED STRICTURE OF THE LOWER END OF THE URETER *

ROBERT H. HERBST, M.D.

CHICAGO

Strictures of the ureter may be due to causes that are either congenital or acquired.

Acquired strictures of the ureter may be classified into those due to (1) trauma resulting from gunshot and stab wounds, postoperative conditions, labor, and passage of calculi; (2) inflammatory strictures, the result of infection. These inflammatory strictures may be classified into, (*a*) those that are the result of direct extension from periurethral infections, (*b*) those in which the infection has either ascended along the mucosa from the bladder, or has descended from the kidney, and (*c*) those resulting from focal infections. Strictures due to tuberculosis will not be considered in this discussion.

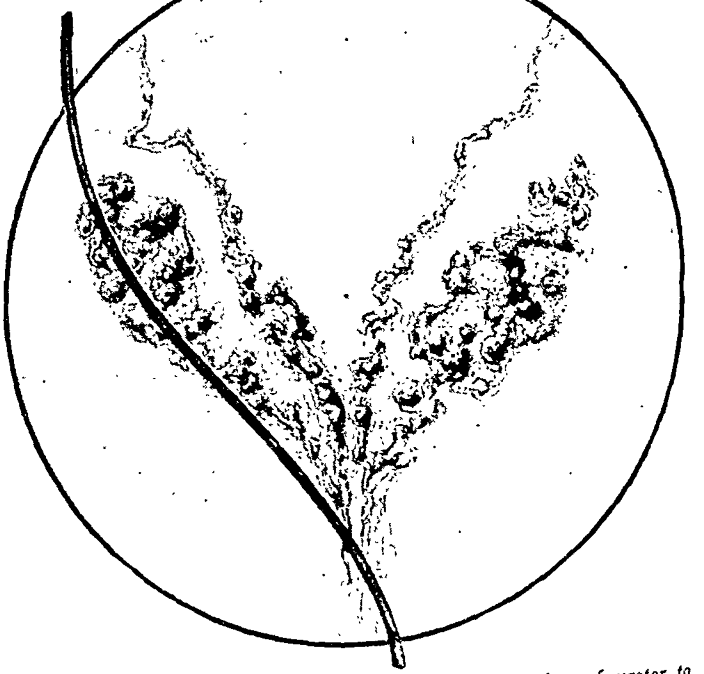

Fig. 1.—From plate made by Belfield showing relation of ureter to seminal vesicle. Vesicle filled with collargol solution. Roentgen-ray catheter in ureter.

Hunner,[1] in his excellent report of "One Hundred Cases of Ureteral Stricture," believes that focal infections play an important rôle in the etiology of ureteral strictures. He states that he is firmly convinced that "The majority of ureteral strictures, excluding those of tuberculous origin, should be classified as simple chronic strictures and that they have their origin in an infection carried to the walls of the ureter from some distant focus, such as diseased tonsils, sinuses, teeth or the gastro-intestinal tract." His cases have to do entirely with women, and I can therefore understand why he omits the infection of the seminal vesicles among these foci.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Hunner, G. L.: Bull. Johns Hopkins Hosp., 1918, 29, 1.

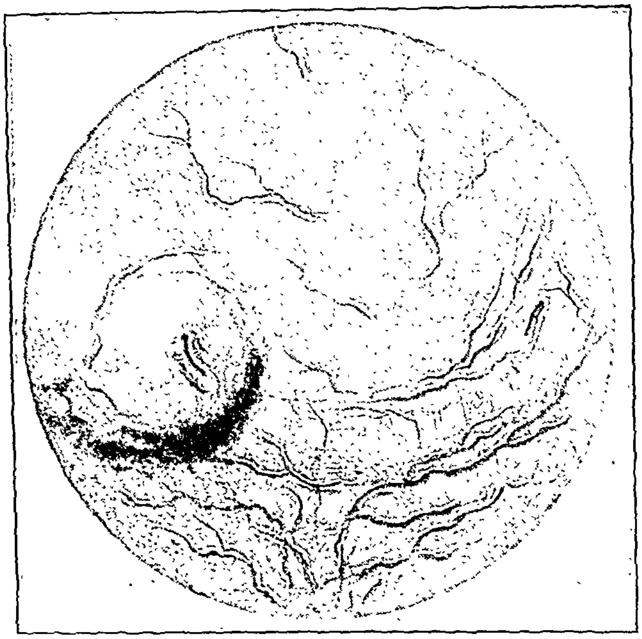

Fig. 2.—Cystoscopic view showing ureterocele of right ureter caused by stricture of lower end of ureter.

Strictures resulting from infection of the seminal vesicles, either by direct extension from these organs, or possibly by organisms of focal origin, are the type to which I shall give chief consideration.

CONGENITAL ORIGIN OF STRICTURE

In the review of some of the earlier literature on the subject of stricture of the ureter, one is struck by the frequency of congenital origin of reported cases. In Bottomley's[2] extensive review we find that most of his reports are those of children, and are unquestionably due to congenital conditions. However, it is difficult to believe that some strictures, especially those showing no symptoms until middle or later life, are of congenital origin. As quoted by Moloney,[3] "How do you explain the delay in development in symptoms until adult life of obstruction of the ureter, when the cause is evidently congenital?" Barringer[4] in 1913, reporting a case of unilateral kidney calculus complicated by ureterocele of the opposite side, stated: "A ureterocele is a dilatation of the intravesicle portion of the ureter. This dilatation is dependent on a narrowing or stricture of the ureteral opening. It is probable that this strictured condition is always congenital, notwithstanding that such a condition has been attributed to the passage of calculi or blood clots through a ureter." Notwithstanding these earlier opinions of congenital origin of these strictures, one finds a gradual tendency toward the belief in the acquired origin of many of them found in middle and later life. Walther[5] believes that stricture of the ureter is not as rare as we have been led to believe, and states that it should be remembered that this condition may be a possible cause for some of the intractable cases of renal infection failing to respond to the usual treatment.

INFECTING ORGANISMS AS A FACTOR IN STRICTURE

The principal organisms that play the rôle of the exciting etiologic factors in the primary inflammatory stage of stricture of the lower end of the ureter are the colon bacillus, the pus coccus and the gonococcus. In the past it has been commonly believed that the gonococcus played a very small rôle in the production of strictures in this region, owing to the infrequency of infection of the bladder mucosa by this organism. However, I am satisfied that the gonococcus is responsible for no small number of strictures that occur in this location in the male, and that the preexisting infection of the ureteral wall occurs by direct extension from its closely approximated neighbor, the seminal vesicle. I shall later give briefly the history of a case which illustrates this point.

In the literature there are reported numerous cases of strictures of an inflammatory nature spreading to the ureter from adjacent organs. In 1902, Morgan[6] reported a case in which, after numerous operations on the urinary tract, he found the cause of the trouble to be due to an obstruction of the lower end of the ureter, caused by the binding of the ureter to the seminal vesicle, the result of an inflammatory process which had long existed in the vesicle. Belfield,[7] in a discussion on the subject of pus-tubes in the male, stated "The intimate relation between the juxtavesical ureter and the seminal duct seems, therefore, responsible for considerable kidney and ureter disease hitherto unexplored."

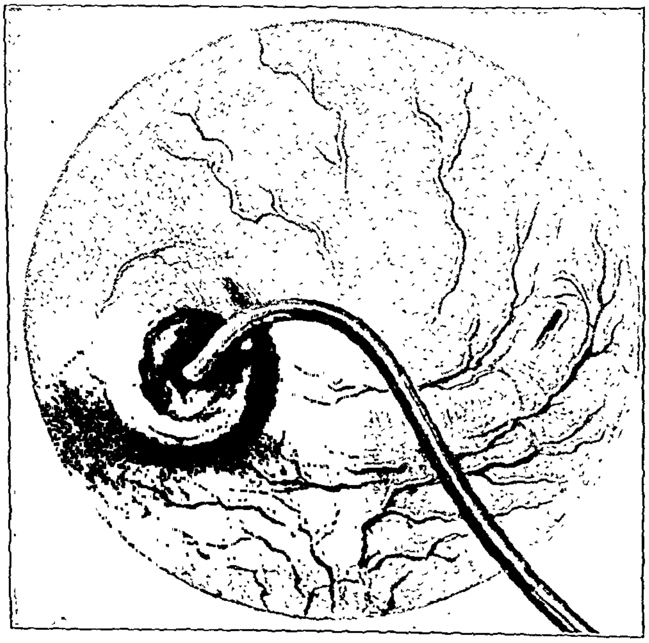

Fig. 3.—Indentation of ureterocele made by attempt to enter strictured extremity of ureter.

[6] Morgan: Ann. of Surg., 1902, p. 528.
[7] Belfield, W. T.: Tr. Am. Urol. Assn., 1909, 3, 13.

McNeill[8] reported two cases of inflammatory strictures of the right ureter due to a pelvic abscess following ureterotomy of the left ureter. Frank,[9] in discussing the causes of ureteral obstruction, gave as a cause an extension of inflammation from infection of the uterus and its appendages. Again, we are all familiar with the condition found in the bladder, known as edema bullosum, commonly due to the gluing of a pus-tube to the bladder wall. If the above conditions are possible, it seems more than likely that an infection going on in the seminal vesicles may spread to the wall of the ureter.

The *pathogenesis of these strictures* is quite similar to that of strictures of the urethra. Let us here briefly consider the course of development of a stricture in the urethra.

First, we find the infecting organism (usually the gonococcus) destroying areas of the superficial mucosa, or what I choose to call the rubber coat of the urethra. The destruction of this mucosa is followed by infiltration of urine with its chlorid constituents. It is the chlorids which have largely to do with connective tissue proliferation and subsequent contraction of the involved area. In the development of strictures in the lower end of the ureter, we find an analogous condition, but reversed in its course. The infection spreads from the vesicle through the outer coats of the ureter, finally involving the lining mucosa with subsequent infiltration and connective tissue proliferation. For this reason some of the strictures become very dense, hard and fibrous, and take on the form of the well known impassible stricture of the urethra. The two cases reported are of this type.

REPORT OF CASES

Case 1.—M. F., aged 30, gave a history of gonorrhea contracted in 1910. The urethra discharged profusely for a number of months, during which time he developed an infection of his right epididymis, for which both the right epididymis and the testicle were removed. The urethral discharge, accompanied by a severe perineal pain, continued intermittently for five years, and in 1913 an "osteopathic surgeon" made a perineal incision of some kind which left the patient with a fistula opening into the bulbous urethra.

He was admitted to my clinic in August, 1915, and, on examination, the perineal fistula mentioned in the foregoing was found, also both seminal vesicles were greatly enlarged and hard. He complained of pubic pain, and for this reason a cystoscopic examination was made which revealed a normal bladder and both ureters perfectly patent. At this time I made a perineal section and closed the opening in the urethra. He was given massage and instillations, with a hope of clearing up the vesiculitis, but after a few weeks he failed to return for treatment. Two years later, in December, 1917, he returned to the clinic, still complaining of his old condition, also of severe pain in the lower right abdomen which radiated upward toward the region of the right kidney. His vesicles were found to be in about the same condition as when he left, for the relief of which I performed a bilateral vesiculotomy. At this time a cystoscopic examination was again made, and, to my surprise, I found a well marked ureterocele on the right side of the bladder, with the orifice of the right ureter located at its summit. Numerous attempts to enter this orifice with small ureteral catheters and bougies were not successful. The roentgenogram of the entire urinary tract was negative. From these findings, the diagnosis of acquired stricture and ureterocele of the right ureter was made. After several attempts, I succeeded in cutting the strictured orifice with a hook-shaped knife used through a Senn operating cystoscope. The small opening was further enlarged with scissors used through a Buerger operating cystoscope. The proximal end of the stricture has not been cut, but I am able to enter this with a small bougie, and expect to succeed in dilating this part of the stricture. I report this case because it illustrates that this stricture evidently developed between the two cystoscopic examinations, between which a period of two years elapsed, also that the stricture had its origin in the violent and persistent infection of the seminal vesicles.

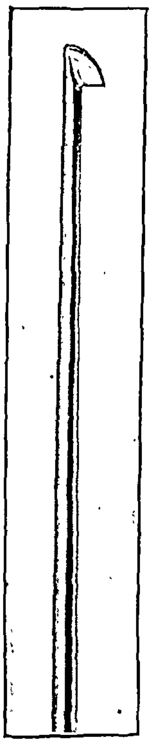

Fig. 4.—Hook-shaped knife used in cutting stricture.

The most common and pronounced symptom is pain, which very frequently is that of a typical renal colic, as illustrated by the following case:

Case 2.—W. G., aged 55, single, stated that some years before he had developed a gonococcus infection which persisted for more than a year and which was accompanied by bladder symptoms, that is, frequent and imperative urination. He consulted me in September, 1913, complaining of a periodic colic-like pain in the back, which was referred to the region of the right kidney. These attacks of pain had come on about every week or two during the previous six months. They were very severe in character, requiring morphin to relieve them. I had the opportunity of seeing him in two of these attacks, and can state that they were typical of renal colic. Examination showed the prostate and seminal vesicles enlarged, the expressed specimen from which contained many pus cells. Cystoscopic examination revealed a normal bladder mucosa. In attempting to catheterize the ureters, I found a complete obstruction of the left ureter, just within the orifice. The right side was found perfectly patent. A roentgenogram of the entire urinary tract showed a small shadow which might be located near the lower end of the left ureter. After numerous unsuccessful attempts to enter the left ureter with very small ureteral bougies, a diagnosis was made of stricture of the lower end of the left ureter. Several attempts to cut the strictrue through an operating cystoscope failed. A suprapubic cystotomy was then made and a small, hook-shaped ureteral knife was forced through the stricture and, by its withdrawal, the entire narrowed portion of the ureter was cut through. A small ureteral curet brought out some fine pieces of gravel which had collected at the proximal end of the stricture, and which had probably been responsible for the shadow seen in the roentgenogram. A No. 8 ureteral catheter was now readily admitted. This patient has been seen and cystoscoped a number of times during the last four years, and the stricture does not show any tendency to recur, nor has he been troubled again by the attacks of colic-like pain.

ETIOLOGY AND TREATMENT

The spasmodic character of these attacks is likely due to complete obstruction of an already very narrow outlet of the ureter. This obstruction may be due to the admission of a pus plug, or a small piece of gravel, into the stricture area, or may be due to the same cause as is found in acute retention of the urine caused by stricture of the urethra. Under these circumstances, the pressure of the urine from behind produces an edema of a canal, already very much narrowed with resulting temporary complete obstruction. The attack promptly subsides on the passage of the obstructing foreign body, or the disappearance of the edema. The pain may be of a constant, dully aching character, referred to either side of the suprapubic region, or not infrequently radiating along the course of the ureter toward the kidney. I have seen

---

8. McNeill: New York Med. Jour., 1917, **106**, 786.
9. Frank: Interstate Med. Jour., 1914, **21**, 1209.

cases of seminal vesiculitis in which the most prominent symptom was this radiating pain along the ureter, and, on catheterizing the ureter, have found what I thought at the time to be a small meatus. However, the pain disappeared after a number of dilatations of the orifice of the ureter. I think it is possible that these were cases in which there was an incipient stricture of the lower end of the ureter. I am also of the belief that in some of my cases of pyelitis which I thought I cured by pelvic lavage, the patient derived more benefit from the passage of the ureteral catheter and the dilatation of a stricture of large caliber, than from the lavage. In such cases, the urine may be perfectly negative during the attack of colic, and may show pus after its subsidence, the pus coming from the infected kidney pelvis after the stricture allows passage of urine from the affected side.

The patients may also have chills, fever, and gastro-intestinal symptoms, as one observes in an acute obstruction of the ureter from other causes.

The differential diagnosis of these strictures from the symptoms is necessarily difficult. However, the cystoscope, the ureteral catheter, the olive-tipped bougie, and the roentgen ray with pyelography are absolutely essential, and will usually help one in clearing up these cases. The olive-tipped bougie is extremely valuable in the diagnosis of stricture of large caliber. When the stricture is very small, or even impassible, the ordinary ureteral catheter will clearly define the condition. In the latter type, we frequently find a decided bulging of the end of the ureter into the bladder—the condition known as ureterocele.

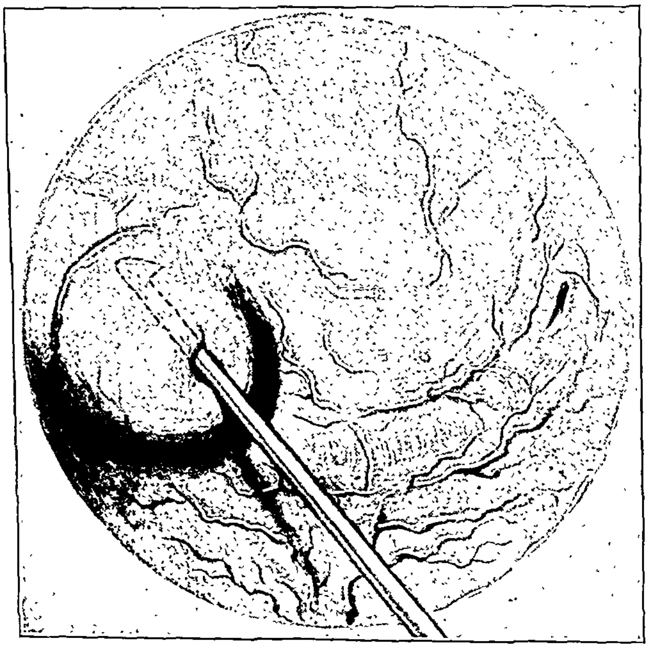

Fig. 5.—Introduction of hook-shaped knife into the strictured area.

IMPORTANCE OF EARLY DIAGNOSIS

Too much importance cannot be placed on the early diagnosis of this condition, since we know that as the stricture becomes more organized, and contracts, the changes in the kidney become more serious.

Strictures of large caliber can usually be readily dilated by means of catheters, bougies and ureteral dilators. In those cases in which, on repeated attempts, we are not able to enter the strictured area, a cutting operation, either through an operating cystoscope or through a suprapubic opening, is indicated. Where this is impossible reimplantation of the ureter, or even nephrectomy, may be necessary. A hook-shaped knife, used in the two cases reported in this paper, has proved very useful in the treatment of those cases requiring a cutting operation, either through the cystoscope or through the opened bladder. To prevent subsequent contraction and recurrence, it is well to practice dilatation for some time following the cutting operation, as is commonly done in operations on the urethra. In cases in which the seminal vesicles are still the seat of infection, treatment must also be directed to these organs, either by stripping, or by one of the operative measures, such as vasotomy or vesiculotomy.

The prognosis necessarily depends on the amount of destruction produced in the kidney. In the cases in which serious changes have occurred in this organ, especially those of long standing, little benefit may be expected from either dilatation or cutting of the strictured area. Therefore, I again call attention to the importance of an early diagnosis.

SUMMARY

1. Strictures of the lower end of the ureter occur more frequently than is commonly believed, and not a few of them are of the inflammatory acquired type.

2. Strictures of this part of the ureter may result from infection spreading from an adjacent seminal vesicle.

3. Strictures in this locality play an important rôle as the etiologic factor in some of the obscure infections of the kidney.

4. The importance of early diagnosis and treatment, before serious changes occur in the kidney, cannot be too strongly emphasized.

ABSTRACT OF DISCUSSION

Dr. V. D. Lespinasse, Chicago: This paper brings up the question of stricture of the ureter. There is no question that slight disturbances of the ureteral lumen will produce marked symptoms and marked trouble. My observation is that there is a tendency to diagnose stricture of the ureter when there is no stricture there. If the catheter goes in a centimeter or two and cannot go any farther, the inference drawn by many is that a stricture is present. This is not so. When the catheter does not go clear to the kidney the diagnosis of ureteral stricture from this fact is not permissible. The diagnosis of stricture from the use of the catheter is quite difficult. According to Hunter's teachings, stricture of the ureter is an extremely common condition. Strictures of the ureter, particularly in the lower end of the ureter, are, at least in many cases, due to infections of the vesicles. The perivesiculitis causes a periureteritis with infiltration and loss of elasticity in the ureteral walls. Whether such a lesion should be called a stricture is doubtful, although it really is a stricture in the strict anatomic sense; but it may be simply an infiltration of the wall of the ureter, the elasticity of which is interfered with, with no real narrowing, except that in the strict sense of the term it has lost its elasticity. Of course, the treatment there is to remove the infection from the vesicle, if possible, and dilate the ureter by the use of a sound or bougie.

Dr. William F. Braasch, Rochester, Minn.: I question very much the possibility of making a diagnosis of stricture of the ureter by means of the ureteral catheter alone. Physiologic and anatomic changes in the ureter may give a sense of obstruction to a catheter which may lead us to believe we are dealing with a stricture. I have frequently met with such obstruction where no dilatation of the ureter above the apparent obstruction could be demonstrated in the ureterogram. We also must recognize the fact that some ureters are of much larger caliber than others. I have frequently observed definite ureteral obstruction in normal individuals who had no abdominal pain nor any other evidence of ureteral involvement where it was impossible to introduce a No. 6 catheter up to the renal pelvis. There are so many other causes for obstruction to the ureteral catheter that it is quite impossible to make a diagnosis of stricture of the ureter because of such obstruction alone.

Although strictures of the ureter unquestionably do exist, I am certain that they do not occur as frequently as some observers would lead us to believe. I am under the impression that postmortem pathology does not bear out the assumption of the frequency of the stricture of the ureter. When found in conjunction with renal infection, it is consequent to such infection and not an etiologic factor. Actual stricture of the ureter cannot be cured by simply passing a catheter or by a single dilatation. On the contrary, it usually requires repeated dilatation at regular intervals as long as the patient lives.

Dr. John R. Caulk, St. Louis: There are two types of ureteral stricture, one in which there is a stricture and the other in which there is not, the latter group predominating. I am in hearty accord with what Dr. Braasch said. I have been impressed with the infrequency of true strictures of the ureter from intra-ureteral causes aside from tuberculosis and an occasional stone impaction. Strictures are not infrequently due to implications in a neighboring inflammation, such as seminal vesicle and pelvic inflammatory diseases. It has been my experience that the most important type of stricture of the ureter and the one which has caused so much confusion and, I believe, false reports, is the spasmodic stricture, or rather the spasmodic contraction of the ureter in the vicinity of an outside inflammation, particularly the seminal vesicles, and it is this condition that I wish to bring to your attention as being responsible for many of the so-called strictures. With the ureter catheter or with bougies it is impossible for any one to differentiate between them in all cases. I want to impress on you the value of large doses of atropin as a means of diagnosis between stricture and spasmodic stricture. Atropin will help the patient out of trouble very often. More attention must be paid to the tissues around the ureter and to ureteral spasm.

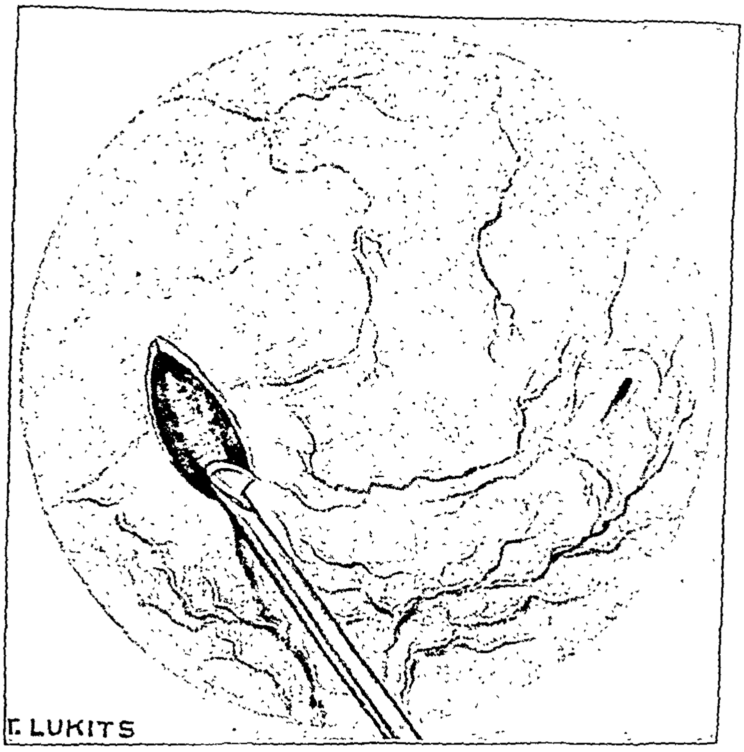

Fig. 6.—Incision of strictured area produced by withdrawal of hook-shaped knife.

Dr. Granville MacGowan, Los Angeles: Strictures occur in the ureter just as in any other tube lined with a mucous membrane, arising from influences internal or external to the ureter itself, and some are prenatal. In my experience, strictures of the ureter are usually due to pelvic troubles that produce adhesions followed by contractions in the ureter itself. Acute appendicitis sometimes produces obstructions of the ureter and causes renal colic, but that passes away along with the removal of the appendix or the subsidence of the attack. Chronic appendicitis, in which the appendix becomes bound down in the pelvis in a matted mass of inflammatory tissue, involving the ureter, sometimes will obstruct the ureter, causing Dietl's crises. I have seen two cases of this kind. There is no valid reason why stricture of the ureter should not follow the passage of a stone, although we know it does not do so usually, yet occasionally the injury must be sufficient to cause contracture especially in persons who have the tendency to keloidal degeneration.

Atropin had been used to relax these attacks. Spinal anesthesia alone will relax a patient and allow the differential diagnosis between stricture of the ureter and muscular spasm of its walls. I have three specimens of ureters which show very distinctly strictures within the bladder wall. In one of them, during life, I could pass a catheter very readily; another I never did get a catheter through. The third is merely a postmortem specimen. There can be no just contention that this disease does not exist, but it is not nearly as frequent an occurrence as urologists think it is.

Dr. William M. Spitzer, Denver: I do not know whether these strictures are true strictures or not. I have met them very frequently in cases of seminal vesiculitis. I know that I cannot pass a catheter more than 1½ c.c. That may be due to outside pressure, or it may be due to stricture, but it is very common, indeed.

Dr. Gustav Kolischer, Chicago: Stricture is caused by the narrowing of the ureteral lumen, due to permanent pathologic changes in its walls. Compression is a temporary condition, due to extraneous causes. There is no doubt that such a condition will form an obstruction to the catheter. You will very rarely find true stricture of the ureter unless after infection. A simple obstruction to passing the catheter does not prove the presence of a true stricture. It very often happens after a gynecologic operation that either on one side or the other you cannot pass a catheter, but that may be due to distortion of the ureter and not to stricture. There is only one way of proving that a stricture exists, and that is by passing an olive-tipped bougie or raying with a contrast fluid. If repeated examinations show the same result, then we have to deal with a permanent condition and can make a diagnosis of stricture.

I have always been very doubtful, just as Dr. Braasch is, as to whether it is possible to cure a ureteral stricture by inserting bougies. I cannot imagine any circumstances in which a ureteral bougie could overcome the resistance of a real ureteral stricture. If this bougie was sufficiently hard and resistant to stretch the cicatricial wall I would be afraid to use it, because I would be afraid of perforating the wall. I believe, however, that it is possible occasionally to clear up pyelitis by regular catheterization. I agree with Dr. Braasch that we find a number of normal individuals in whom you are hardly able to enter the ureteral mouth at all, but that is not due to stricture, but to a congenital narrowing of the opening.

The rather energetic treatment recommended by Dr. Herbst in some of his cases, that is, an incision high up into the vesical wall, is rather risky. Real strictures of the ureter may occur after extensive gynecologic operations leading to extensive denudation of the ureter and followed by ureteritis, as proved by postmortems when those patients died from subsequent pyonephrosis.

Dr. J. L. Boogher, St. Louis: I believe that these strictures indicate a pathologic change in the structure. That can take place from mere pressure; there must be a formation of fibrous tissue in the structures which is brought about by the production of cells in the tissues which cause the lessening of the blood pressure from the normal mucous membrane. The necessity on the part of nature for the production of this tissue is either because of infections or from the pressure of the mucous membranes. Without the development of the spindle-shaped cell or cells of lessened blood requirements strictures cannot form. Spasmodic strictures may occur, but they cannot be called strictures; they are simply an element which produces a temporary tightening of the lumen of the vesicle; but when we have the pressure of foreign tissue brought into any sort of a channel, I do not see how the passage of any sound can change the character of that tissue. The cause of the production of the peculiar tissue which is there must be discovered and removed. I do not see why a catheter would not cause some irritation and add to the stricture more than it would detract from it.

Dr. Bernard Erdman, Indianapolis: With reference to Dr. Braasch's remark about the normal narrowing of the ureter, it seems to me that the meatus of the ureter bears the same relation to the ureter that the meatus of the urethra does to the urethra. It is probably the narrowest portion of the entire canal. Another point that ought to be brought out is this: All ureters do not enter the bladder in the same manner. It is sometimes a very difficult problem to pass a ureter catheter in an individual in whom I absolutely suspect no stricture at all. I would like to take issue with Dr. Boogher about the spindle cells, and I think we have a good deal of trouble with round-cell infiltration, too.

Dr. J. Dellinger Barney, Boston: I would like to get an expression of opinion as to the use of papaverin, mentioned by Dr. MacGowan and others. I have tried it in several cases, and have had about as good results by simply attempting to pass a catheter.

Dr. William F. Braasch, Rochester, Minn.: We have used papaverin in the endeavor to remove stone from the ureter in twenty-five or thirty patients. I am under the impression that papaverin was not the greatest factor in the majority of instances in which we were successful. When a stone can be removed by cystoscopic methods, manipulation by the ureteral catheter so as to shift the stone's position is probably the most important factor. Since this is usually done when introducing papaverin, the latter has been given greater credit than it deserves.

Dr. Robert H. Herbst, Chicago: I agree with the statement made by Dr. Braasch and Dr. Caulk, that the ureteral catheter is of very little value in the diagnosis of stricture of the ureter. There are many conditions which may cause the interruption of the catheter, both into and along the ureter, and one must be very cautious in making the diagnosis in this way without other findings. This is also true of the olive-tip bougie. When one is able to enter the narrowed portion with a catheter, the injection of a contrast fluid and the roentgen ray are of great value in making the diagnosis. However, this is not possible when the obstruction will not admit even the smallest size catheter. The two cases reported were both of the impassable type.

The cases of strictures reported in this paper were of the type which are found at the extreme lower end of the ureter and which have been preceded by severe inflammatory changes in the seminal vesicles. I believe that these obstructions are due to inflammatory changes in the wall of the ureter and not adhesions binding the ureter to the seminal vesicles. The wall of the ureter is too rigid to be compressed in this way. In opening the lower end of the ureter we must keep in mind the danger of making the incision too long. The ureter is inserted into the wall of the bladder for a distance of 2.5 c.c., and the incision must be kept within this limit.

The Microscope.—The first compound microscope was probably invented by the Middleburg lens grinders, Johann and Zacharias Jansen, about 1590.

THE RATIONAL ETIOLOGY AND SATISFACTORY TREATMENT OF DACRYOCYSTITIS *

W. R. THOMPSON, M.D.
FORT WORTH, TEXAS

The man who first suggested a lacrimal probe was thinking along scientific lines. By its use he hoped to remove the obstruction from the nasal duct, and restore its normal function. His disappointment came, however, when he learned, from repeated efforts on patients in whom the probe could be passed through the duct into the nose, that in most instances the tendency to an immediate closure was so great that the hope of draining the sac of its infectious contents had to be abandoned. The failure of the probe to give relief by drainage suggested the use of the style, which proved to be unscientific in principle and unsatisfactory in results.

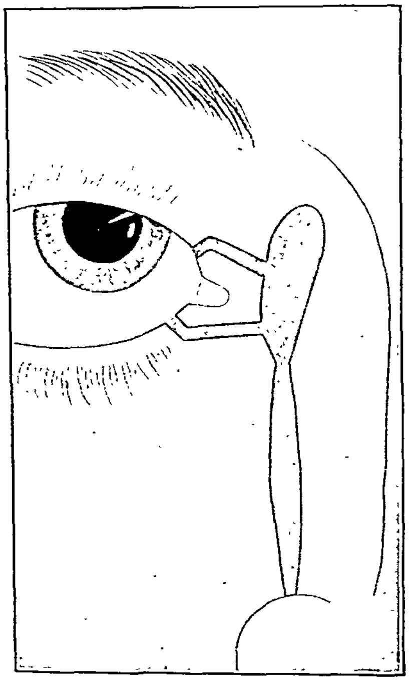

Fig. 1.—Normal sac and nasal duct.

For several years all contributors to this subject seem to have given up the idea of drainage or the restoration of the normal function of the lacrimal sac and nasal duct, and instead have directed their energies to sac destruction or removal, or direct drainage into the nose.

It is not my purpose to criticize the different methods of treatment. In my opinion, however, all methods depending for their success on the complete destruction of the function of the sac and duct are more or less faulty.

In the absence of adequate postmortem information, it is impossible to determine the exact cause of nontraumatic stricture of the nasal duct. Our textbooks say that inflammation of the nasal mucous membrane and obstructions resulting from the enlargement of the inferior turbinates, nasal polypi, etc., are among the most common causes. There appear to be some very good anatomic reasons for the belief that other and possibly more rational causes exist.

The nasal end of the nasal duct is by far the best protected of all openings entering the nasal cavity. Nature evidently realized the importance of having this duct perform its function properly at all times; to that end she displayed great wisdom in the construction and location of the inferior turbinates. The duct, as all know, enters the nasal cavity with rather an expanded orifice, immediately beneath the anterior end of the inferior turbinate. The upper border of this bone is thin and is connected to various bones along the outer wall of the nose; the lower border is free, thick, and cellular in structure. The outer surface, looking toward the opening of the duct, is concave and assists in the formation of a large and well ventilated cavity — the inferior meatus, into which the duct opens. When this bone becomes hypertrophied, the enlargement takes place on the inner or

---

* Read before the Section on Ophthalmology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

can be employed and in a very large percentage of cases the trouble relieved in a few days.

My experience with this method extends over a period of two and one-half years, during which time cases of epiphora, mucocele and purulent dacryocystitis have been cured and the function of the sac and duct restored. Since most of these patients get well with one operation and no after-treatment, it is very difficult to get accurate statistics, as they all return home immediately, and some of them live in remote localities. Fortunately I have been able to follow a variety of cases, which prove beyond question the value of the method. The following cases are given as illustration:

REPORT OF CASES

Case 1.—The first person to be operated on by this method was a man, aged 65. He gave a history of having had a purulent discharge from the sac for twenty years. I had treated him with probes sixteen years before, with no success. The sac was considerably dilated, as indicated by a decided depression after he expelled the pus, which he did several times daily. He was well in ten days, kept under observation for two years, and has had no further sac infection, overflow of tears, or lacrimal conjunctivitis.

Case 2.—A woman had purulent dacryocystitis of long standing, and gave a history of two lacrimal abscesses. A fistulous opening into the sac existed at the time of operation. When seen, five weeks later, she said that she was well a week after the operation. Cocain passed readily into the nose and mouth from the conjunctival sac.

Case 3.—A man had mucocele of long standing, with severe lacrimal conjunctivitis. He was well in a week after operation. He has been seen monthly for six months, and has no evidence of his old trouble. Cocain passes through the nasal duct into the nose and mouth.

Case 4.—A woman with epiphora was not benefited by three months of ordinary treatment. She was relieved at once by operation, and has been under observation for seven months without recurrence.

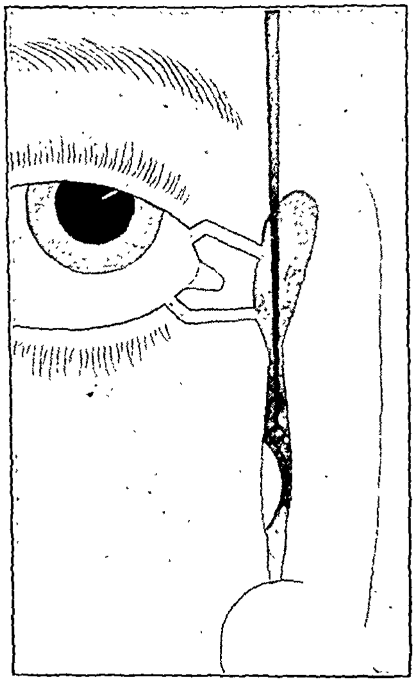

Fig. 3.—Curet in position for augur-like motion.

CONCLUSIONS

1. The simplicity of the method makes it attractive.
2. It requires but little skill to perform a good operation.
3. The sac and duct should never be irrigated after operation.
4. No loss of time or hospital expense is incurred.
5. No great outlay is required for instruments.
6. Every type of dacryocystitis can be cured, and function of the duct restored.
7. The danger of fracturing the bone, or making a false passage or producing hemorrhage with the probe, is avoided.
8. Thoroughness is absolutely essential to success.

ABSTRACT OF DISCUSSION

Dr. Harry W. Woodruff, Joliet, Ill.: With reference to the etiology of dacryocystitis, as advanced by Dr. Thompson, I believe that he has given us a probable cause for these conditions, the presence of foreign bodies in the nasal duct. We ave had no more satisfactory explanation of the etiology of ronic dacryocystitis with stricture. Perhaps many of you have had the experience of seeing foreign bodies actually lodge in the puncta. Small ones go through easily and may lodge on the mucous surface of the nasal duct. I have a few times removed cilia that had passed into the canaliculus and were too long to make the turn and go down into the sac.

I operated on seven patients by this method. Two of these were cured; at least they have not returned, and they usually return if they are not cured. The remainder were not cured. Dr. Thompson suggested to repeat the operation. I did so on some of them, and I got no results. Dr. Thompson thinks that the cause of failure is lack of thoroughness, but in doing this secondary operation I discovered that I had done the first operation so thoroughly that a great deal of cicatricial tissue had formed. Perhaps my thoroughness, however, was applied in the wrong situation; that is, there had been too much curettement of the sac and not enough of the stricture. One class of cases in which this operation is not indicated is dacryocystitis in infants, congenital dacryocystitis. These cases are all curable by probe and washing when taken very early, and they are curable in one or at most two treatments. In these cases there may be present a membrane about the nasal opening of the duct; as soon as it is broken down an immediate cure follows.

In passing the probe in these young infants, only a few weeks old, it often happens that the membrane is not broken down but is pushed ahead of the probe. You have no means of knowing this, except that when you use the syringe the fluid does not come through into the nose. This is my theory. I have had two cases of that kind in the same family and obtained an absolute cure in each case.

I am not satisfied that Dr. Thompson's method is an absolute cure; neither am I satisfied that it is a failure. I believe that it is a better method than those methods which attempt to make an opening through from the lacrimal sac into the region higher up. In many of these cases we will be compelled to resort to the radical procedure of extirpation of the sac.

Dr. John Green, Jr., St. Louis: Dr. Thompson's statement that the style is "unscientific in principle and unsatisfactory in results" is, in my opinion, rather too sweeping. Given, a narrowing of the bony duct, with simple epiphora, in which the passage of probes of moderate size is possible without the use of force, the wearing of a style not rarely results in a permanent reestablishment of satisfactory drainage. I have operated in six cases of chronic dacryocystitis in the following manner: After cocainizing the sac with 5 per cent. epinephrin cocain solution, the canaliculus is slit freely, and a small probe, say a Bowman 4, is passed to the nostril; a few drops of 10 per cent. cocain with epinephrin is injected into the bony duct. This is repeated twice at intervals of three minutes. During each injection the head is held forward so that any of the solution that reaches the nasal end of the duct will flow out of the nostril. The duct is then dilated rapidly up to 8 or 10 Theobald. The sac and duct are then curetted according to the method described by Dr. Thompson. None of these patients have complained of pain, which I attribute to the free use of 10 per cent. cocain prior to the introduction of the larger probes and curet. Too short an interval has elapsed to speak of ultimate results, but the immediate improvement was very striking, the reestablishment of free drainage and the cessation of pus formation in the sac. I was very glad to hear Dr. Woodruff speak of the use of probes in the dacryocystitis of infants. It is my impression that man of us still reso [illegible] zing methods, allowing these c dren to go mor [illegible], when one or two probings effect a perman

Dr. Arthur E. Prince, Springfield, Ill.: Dr. Woodruff's method of treating infantile dacryocystitis is endorsed. In my experience two probings have been sufficient to cure every case that I have seen, and it would be very unwise, almost criminal, to lacerate the mucous membrane of the canal in a case of that kind. I take exception to Dr. Woodruff's statement questioning the wisdom of opening the sac directly into the nose, and thus obtaining permanent drainage. Three years ago I published a preliminary report in the *Ophthalmic Record* of an operation for draining the sac directly into the middle meatus of the nose. Since that date I have never had occasion to remove a single lacrimal sac, neither have I had recourse to the excellent method of Dr. Gifford for destroying the lacrimal sac with trichloracetic acid. I take exception to the treatment by curetting the nasal duct on the ground that the curettement would probably cause an additional stricture and would be contraindicated in cases of congenital epiphora, as has been pointed out by Dr. Woodruff.

Dr. Harold Gifford, Omaha: I want to compliment Dr. Thompson on his theory and on his practice, if it is as successful as he says it is; and the proof of the pudding is the eating. So far as I know, this method is original with Dr. Thompson. The idea that strictures are commonly due to the accumulation of small foreign bodies at the narrowest portion of the sac or duct is well worth consideration. To account for this we really ought to find that in these people who have these strictures, the lacrimal puncta must be unusually large to allow these foreign bodies to enter. It certainly is rather rare to find any foreign bodies in the sac, but then, as Dr. Woodruff says, the fact that we have all seen a cilium part way through the punctum, shows that a foreign body of appreciable size certainly can make the passage. When I first heard of the method of Dr. Thompson I felt that it was a good way of destroying this duct and of getting a permanent closure, but Dr. Thompson's results indicate that I was wrong. I can easily see how, if his idea is correct, if granulation tissue forms in that neighborhood, the removal of it with a smooth curet might be of very permanent value.

Dr. Melville Black, Denver: I was very much interested in Dr. Thompson's theory of causation. It is not borne out by the fact that most cases of dacryocystitis are double. If this condition of affairs was almost invariably single, the hypothesis of foreign body causation would be much more tenable. But there is some inherent underlying cause. Otherwise, these cases would not almost always be double. In his drawing Dr. Thompson gives the formation and position of the seeming deposits of lime salts, or whatever it is, in the most bulging portion of the lacrimal canal, the portion in which you would not naturally expect the formation of a lime salt deposit. If there was a foreign body in the canal it presumably would not lodge in the largest portion, but in the most closed and dependent portion, and then we would have formed around the foreign body a lime salt deposit.

I take it that his presumption that we have this sort of a formation is purely theoretical. He has not said, in his paper at least, that he has made any dissection of the canal, nor demonstrated the actual presence of a foreign body. Furthermore, as Dr. Green has remarked, it would be well to determine by microscopic analysis of these curettements whether or not anything came from the canal. Everything that we have done, up to the present time, in our endeavor to reestablish the patency of this canal, has been a failure, and if this thing will do it, I want to give it a trial.

Dr. G. Henry Mundt, Chicago: I am rather surprised that some reference has not been made to the inadvisability of splitting the punctum. I have for a number of years watched the splitting up of the canaliculus, and various and sundry other procedures. It is my observation that any procedure on the lacrimal drainage apparatus, of which the splitting up of the canaliculus is part, is unsatisfactory. Dr. Thompson speaks about the importance of epiphora as preceding dacryocystitis. It may be so. I do not know. I never have followed that carefully. But I have done this in all patients who have epiphora: I make pressure over the lacrimal sac, and if there is no secretion in the sac I forget the lacrimal drainage apparatus. I believe that is the best thing to do. Unfortunately, I have not tried this procedure, but the probability of my trying it is precluded by the necessity of splitting up the canaliculus. I think that I shall continue to do Dr. Gifford's procedure.

Dr. W. R. Thompson, Fort Worth, Texas: I am enthusiastic over this method. I believe there is a good deal more to it than the majority are inclined to believe. I do not consider the splitting of the canaliculus a very serious matter. If that is the only pathologic condition remaining after the cure of a case of dacryocystitis, the patient will never complain. One patient on whom I operated a year and a half ago had a mucocele. There was no great amount of pus, but there was a decided mucus deposit in the sac which could be pressed out. I operated after this method, removing the constriction in the duct completely. I want to emphasize that that is the main part of the operation. In this case I did very little to the sac, almost nothing, but I did restore the bony canal to its normal size. That man had never been operated on before. That was the end of the treatment. He has had no trouble since. He has no overflow of tears. The instillation of cocain into the nose passed readily through into his mouth. He had the bitter taste. I could discover no opening in the canaliculus. It apparently had closed up. I do not say that that would be the case in many instances, but it certainly was the case in that particular instance. I do not operate on infants; I do not operate in any case when ordinary means will give relief. But I do operate because of the epiphora after they have resisted the ordinary treatment for a great length of time, and I get good results. Refractive errors should be corrected, but you would not expect refraction to cut any figure in a case where you had epiphora on one side. Watering of the eye might be the result of eye-strain. The cause of epiphora, of course, is to be treated until you are thoroughly convinced that there is no way of relieving it; that it will not get well. In the cases where you have an excessive amount of pus in the sac, you will curet the sac thoroughly and you will make your operation as complete as possible. Curet the sac as well as the canal. Restore the normal caliber of the nasal duct. I do not believe that in any of these cases the bony wall of the duct is changed in the least. I think it is entirely possible to restore the normal caliber of the duct by removing it. After you have curetted it out, including the granulations, then make an application of tincture of iodin and you will get results.

POLIOMYELITIS: NEW DEVELOPMENTS IN THE AFTER-CARE AND TREATMENT

BETTER RESULTS IN RESPONSE TO THE DEMAND

CHARLES OGILVY, M.D.
NEW YORK

The care and treatment of poliomyelitic cases has within recent years fallen to the lot of the orthopedic surgeon. For the first time the opportunity of controlling and supervising the treatment of these patients has been given him.

If the responsibility of the final results rests on the shoulders of the orthopedic surgeon and he has the direction of the case throughout its whole course, better results are anticipated and obtained. By this one does not mean to infer that the cooperation of the neurologist, the internist and the general practitioner is not constantly sought and maintained. Their cooperation is necessary in obtaining the best final results, but the problems involved are essentially and specifically those for the orthopedic surgeon to assume and to solve.

A year ago[1] I reported on a group of 110 cases which has been closely followed for one year. A second year of after-care and treatment has since elapsed, and a survey of this year's work reveals a number of very interesting facts which have not been heretofore recorded. In this paper time will permit me to refer to only two essential points, (1) the return of lost function, and (2) the occurrence of deformity.

---

[1] Ogilvy, Charles: A Report of a Group of One Hundred and Ten Cases of Poliomyelitis from the Acute Onset to the Present Time, The Journal A. M. A., Sept. 1, 1917, p. 691.

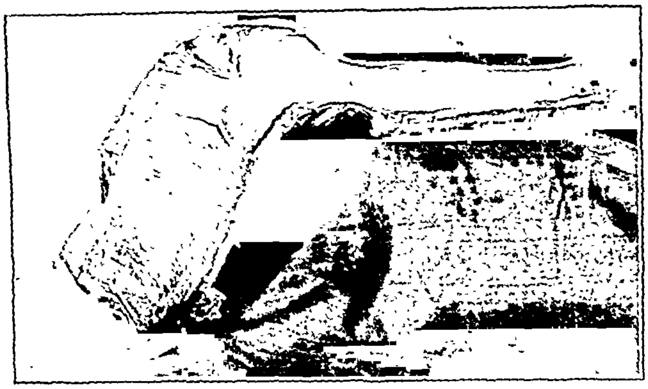

Fig. 1.—Horizontal arm splint for deltoid paralysis. This splint is made of plaster- of Paris and trimmed with adhesive plaster.

In cases of complete flaccid paralysis affecting either a muscle or a group of muscles without any return of function after six months, further treatment is useless so far as the return of function is concerned. The paralysis is permanent in this flaccid type of case in which there is no reestablishment of the communication through the nerve centers of the cord. In my group of cases we have had nine cases in which such flaccid paralysis occurred.

REST AND REST SPLINTS

In the previous paper it was stated that the one greatest factor in obtaining a return of lost function was rest for the muscles affected. I then thought that six months should be the limit of time for such inactivity. I now believe that one year is not any too long for certain cases.

The simplest and most efficient means of obtaining rest is in the use of plaster-of-Paris shell splints. These are light, easily applied, comfortably fitting and the most economical braces we can use.

Of these I wish to call attention to three in particular, first, the arm rest for deltoid paralysis (Figs. 1, 2 and 3). This is a splint in which the arm can be placed in any position necessary. It is bandaged firmly to the body over the clothing and has proved one of the most efficient splints in use. The result has been that of six deltoids primarily involved we have been able to obtain a return of function in all but one case.

The second plaster-of-Paris shell that I wish to mention is one for the spine. The difficulty of preventing a lateral deviation of the spine is very great when there is an inequality of the power of the muscles on either side. Especially is this so after the twelfth month, when it is impracticable constantly to retain the patient in a recumbent position. Figure 4 demonstrates this special brace which I have used. It is a combination of a plaster back and a canvas corset.

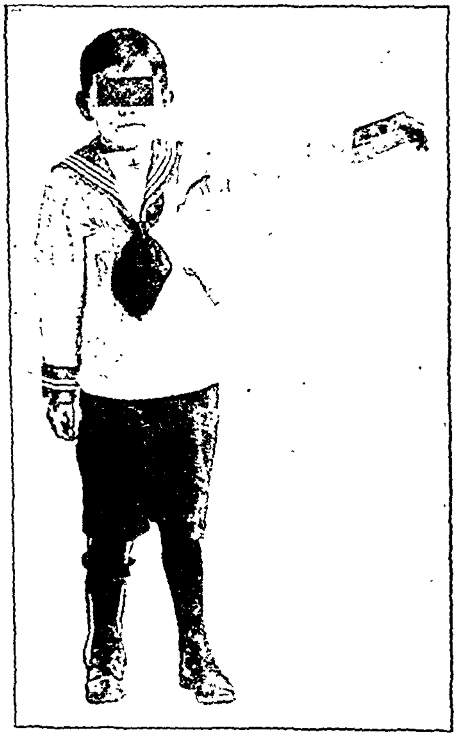

Fig. 2.—Deltoid paralytic splint applied.

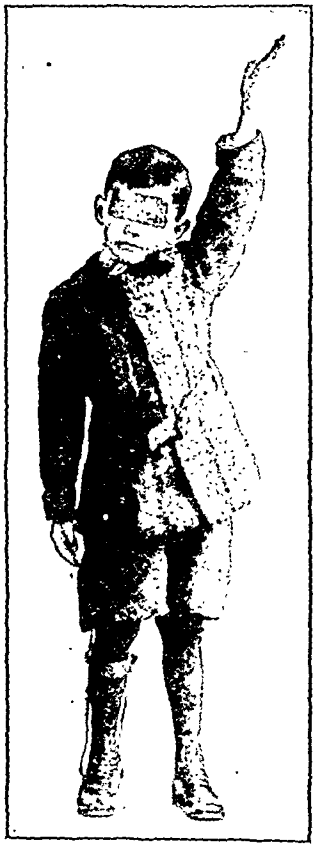

Fig. 3.—Same case; recovery of deltoid.

Emphasis should be made on the necessity of night splints in all cases in which there is a tendency to foot drop or other foot deformity (Fig. 5). Deformities will invariably follow when no such provision is made. One often sees very beautifully applied braces being worn in the day time and the foot allowed to assume positions of deformity during the night. This will ultimately become so marked as to demand operative procedures.

BRACING

There is some controversy and much misunderstanding regarding the employment of braces, both in the profession and among the laity. Some have stated that they "do not believe in bracing." The natural result of such a statement has been that parents have allowed their children to attempt walking without the use of braces, with disastrous results in many instances.

The purpose of braces is to encourage function, not to discourage it, and to prevent deformity. Both of these results are successfully obtained, provided the brace is made sufficiently light. All bracing should be made with as much joint freedom as is consistent with prevention of deformity. It is entirely an erroneous impression that the wearing of a properly applied light brace predisposes to continued weakness of the muscles. This is not the case.

Overfatigue, more than anything else, prevents a return of function, and a proper brace is the best guard we have against overfatigue. It must, however, fit accurately and be as light as possi .

DEFORMIT

There are two deformiti
wish to draw attention.
during the first but d

are those of lateral deviation of the spine and equinocavus of the foot. Either of these deformities may develop gradually as the patient's activities in the sitting and standing posture increase. They are easily accounted for but exceedingly difficult to check. If we could continuously keep these patients on their backs the question would be solved, but this is not practicable. For the milder cases a small light canvas steel corset (as seen in Figs. 6 and 7) with postural exercises has been sufficient to hold these cases in check.

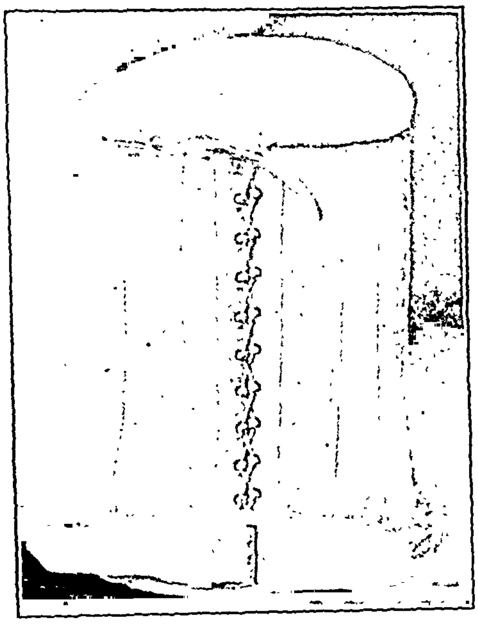

Fig. 4.—Author's plaster-of-Paris canvas corset.

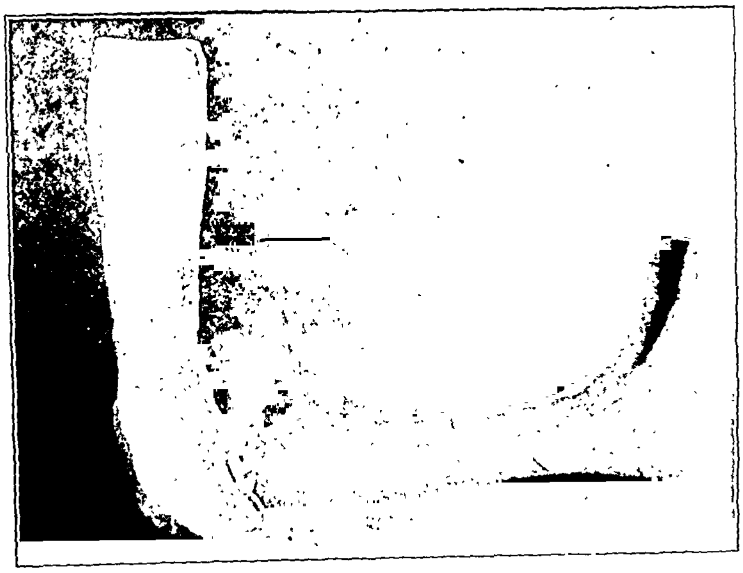

Fig. 5.—Night splints to prevent foot deformities.

The more severe cases have had a plaster-of-Paris posterior shell, splint with a canvas front, as referred to above (Fig. 4). This I cannot too highly recommend, as it has many advantages over the complete plaster-of-Paris corset and at the same time has sufficient corrective force to prevent the development of deformities.

The second deformity referred to is that of equinocavus (Fig. 8). This has developed in two of my cases. In neither of these cases were any of the muscles of the leg completely paralyzed and in neither of them was any deformity whatsoever noted until the twelfth and fifteenth months, respectively, after the acute attack. Note the late date of the development of these deformities. This emphasizes the importance of continuous supervision for at least two years after the onset of the disease.

In cases in which round shoulder, malposture, develops, a shoulder brace should be applied. The lighter and simpler these are, the better. The most efficient is one in common use, which goes very much as a figure-of-eight bandage around each shoulder, being drawn firmly across the back.

MUSCLE TRAINING

I have employed a special muscle trainer whose sole duty it has been to establish systematic muscle training in all cases in which it was deemed advisable. My conclusions in this regard are:

1. The responsibility of muscle training cannot be left to the parents to be properly carried out.
2. Comparatively little value can be obtained by muscle training until the child is over 6 years of age.
3. It should be continued for at least two years.
4. The results obtained are dependent as much on the patient as on the trainer.
5. A great deal depends on the disposition of the child.
6. Muscle training is indispensable in cases in which it is applicable.

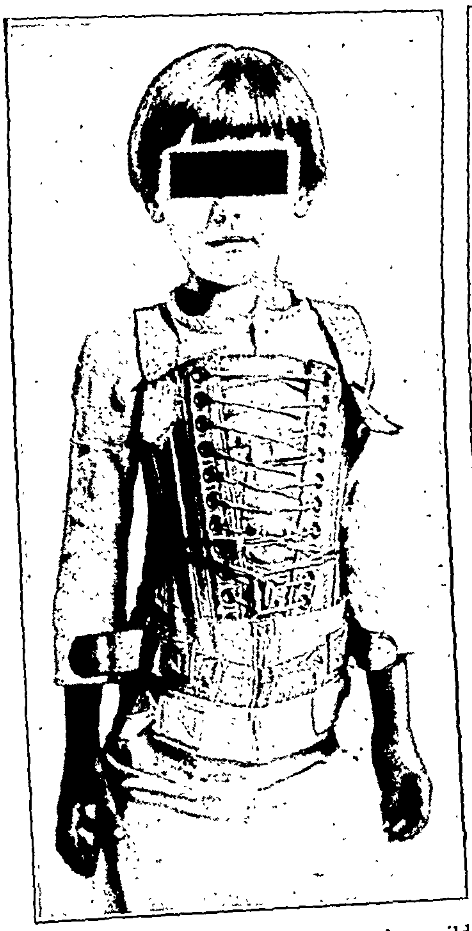

Fig. 6.—Canvas steel corset for mild cases of spinal deformity, front view.

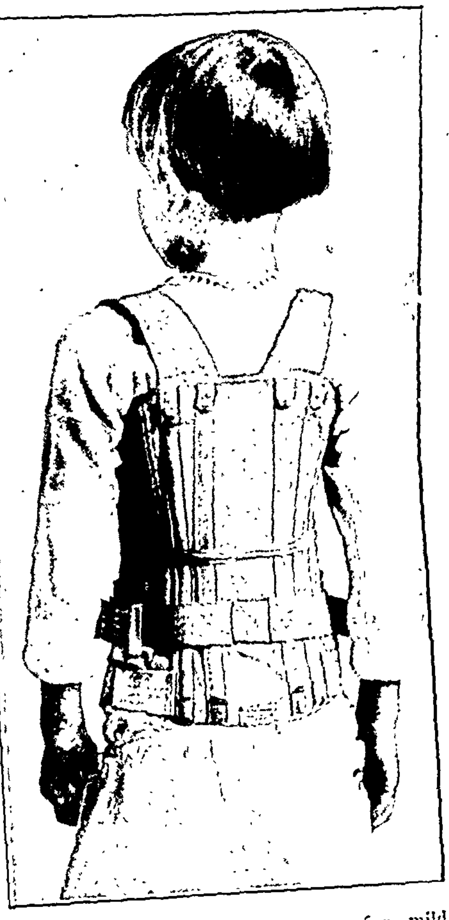

Fig. 7.—Canvas steel corset for mild cases of spinal deformity, back view.

BATH EXERCISES, MASSAGE AND ELECTRICITY

Bath exercises are of the greatest importance and should never be omitted, especially at the stage when the return of muscle function is just sufficient to produce motion. Often such motion is encouraged without fatigue by bath exercises when the same exercises out of the bath would assuredly produce overfatigue. Furthermore, the encouragement obtained by seeing the muscle functionate in the bath is of the greatest value in the development of power. Regular, systematic massage should not be begun before the fourth month. The value of massage is unquestionable. This should be carried on by a skilled masseuse.

Electricity for the purpose of obtaining a return of muscle function has not been used. I cannot see in any instance where it could possibly have resulted in a greater amount of muscle power than has otherwise been obtained.

CONCLUSION

I cannot too strongly recommend that these patients be continuously kept under the same care and supervision throughout. I hope that the work done by myself and others along this line will be of sufficient value to establish a definite course of practical treatment which can be universally pursued in order that the best final results may be obtained in these cases.

The Necessity for Prenatal Care.—In an article on "The State and Prenatal Hygiene" (*British Medical Journal,* Oct. 5, 1918), E. McConnell, M.D., analyzes the death rate of infants under 1 year in the city of Glasgow with reference to the necessity of prenatal care in the interests of the mother, the child and the state. He shows that two thirds of the deaths under 3 months occur in the first month; that in the first week the deaths in both sexes are four times more numerous than in the second week, and about six times more numerous than in the fourth week after birth, while one third of the deaths during the first year occur before the fourth week of life is completed. Adding to these the stillbirths which amount to 4 per cent. of the total births, totalling about 1,200 for Glasgow and about 4,000 for Scotland, McConnell says we have an illustration on a considerable scale of the work to be done by an organized system of prenatal care. These deaths lead directly to the period antecedent to birth and away from the direct influence of environment, and have as their predominant cause what the health officer of Glasgow in a report to the Seventeenth International Congress of Medicine in London in 1913 termed "immaturity" to express the inability of the child to live apart from its mother, and would include infants coming under such designations of disease, etc., as premature, congenital defects, atelectasis, atrophy and debility or wasting diseases.

Military Medicine and Surgery

PHAGOCYTIC EXPERIMENTS IN INFLUENZA

RUTH TUNNICLIFF, M.D.
Contract Surgeon, U. S. Army
CHICAGO

The following experiments were made in an attempt to determine the relation between influenza and the complicating pneumonia and the green-producing streptococcus isolated at Camp Meade, by the late Captain George Mathers.[1] This coccus was isolated from the sputum during life and from the heart's blood, lungs, pericardial and pleural exudates at necropsy.

A report of the bacteriology of the influenza epidemic at Camp Meade was being prepared by Captain Mathers at the time of his death. He isolated a green-producing streptococcus from the sputum in 87 per cent. of 110 cases of influenza and pneumonia examined. The cultures were made on the first or second day of the disease. The influenza bacillus was also isolated in 58 per cent. of the sputum cultures. The coccus appeared in the sputum smears as gram-positive diplococci, 2 microns in length, with slightly pointed ends and a capsule. In cultures they grew in pairs and long chains and showed a capsule. On human blood agar plates the colonies were large (from 0.25 to 0.5 cm. in diameter) green, flat, moist, with regular edges, and had a tendency to become confluent. The colonies often showed umbilication in forty-eight hours. Cultures of this organism were not soluble in bile. They grew as a flocculent growth in glucose and plain broth, the fluid generally not remaining clear. They fermented glucose, lactose and saccharose, but neither mannite nor inulin, except in one instance. Sputum injected intraperitoneally into mice was virulent, killing them within twenty-four hours. These cocci were not agglutinated by type pneumococcus serums.

It is generally recognized that opsonins are the only antibodies easily demonstrated in streptococcus infections. Agglutination tests with the serum of five influenza and two pneumonia patients examined during the attack and convalescence were negative with three strains of this streptococcus, even in so low a dilution as 1:2. Opsonic experiments were therefore made. Sputum strains were generally used, as those isolated at necropsy were usually not phagocytable, presumably because too virulent. *Micrococcus catarrhalis* and *Streptococcus hemolyticus* were used as controls. The influenza bacillus frequently associated with the green-producing streptococcus was not tested at Camp Meade because this bacillus is usually spontaneously phagocytic.[2]

The opsonic power of the blood serum was estimated by the dilution method. The normal and immune serums were diluted with physiologic sodium chlorid solution to determine the point of opsonic extinction—the point at which induced phagocytosis recognizably exceeds phagocytosis with salt solution. Normal human washed leukocytes were used. The mixture of serum, leukocytes and bacterial suspension was incubated at 37 C. for fifteen minutes and the smears then stained with Wright's stain. Fifty polymorphonuclear leukocytes were counted and the number taking part in phagocytosis noted.

---

[1] Captain Mathers died October 5, from influenzal pneumonia, contracted while engaged in this work.

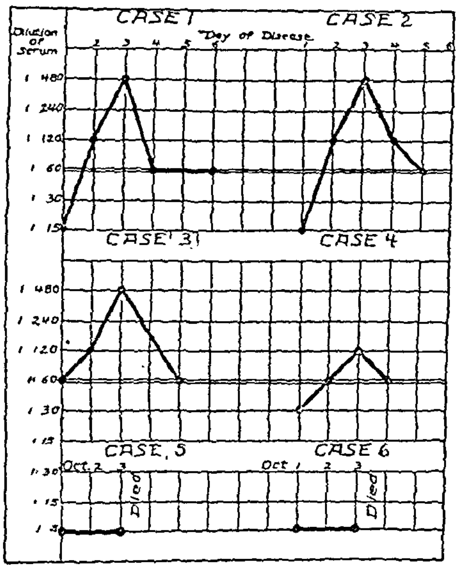
[2] Tunnicliff and Davis: Jour. Infec. Dis., 1907, 4, 66.

The serum of four patients with acute influenza was examined daily for its opsonic power. On the first day of the disease the opsonic content in three was below normal. On the second or third day the opsonic power of all rose well above normal, remaining high a day or two and then returning to normal (Cases 1, 2, 3 and 4 in the accompanying chart).

Ten severe cases of pneumonia following influenza were also examined in the same way. The serum showed little or no opsonins for the coccus (Cases 5 and 6). In two instances the opsonic power increased slightly with improvement in the patients' conditions, decreasing again when the patient became worse. The opsonic power of two patients who recovered returned to normal.

These opsonic changes in influenza and the complicating pneumonia were specific for the green-producing streptococcus, no fluctuations in opsonins being observed with either *Micrococcus catarrhalis* or *Streptococcus hemolyticus*.

Later in Chicago, the serum of [illegible] patient with influenza and [illegible]h influenzal pneumonia [illegible]ined for their opsonic [illegible] for the green-producing streptococcus and the influenza bacillus. Two strains of the influenza bacillus isolated from influenzal pneumonia lungs at necropy [illegible]e used; one showed practically spontaneous phagocytosis, the [illegible] not sufficient to interfere with the experiments. All four patients showed during the acute stage no opsonins for the streptococcus, the point of opsonic extinction for the control being 1:60. One patient died. The serum of the three that recovered showed, as the symptoms subsided, a high opsonic content, the point of opsonic extinction being 1:480, 1:240 and 1:480. The negative phase in these influenzal pneumonias for the green-producing streptococcus is much more pronounced than is generally observed in other acute infectious diseases. None of these serums showed any changes in opsonins for the influenza bacillus.



Cases 1, 2, 3 and 4, opsonin curves for the green-producing streptococcus of the serum of influenza patients who recovered. Cases 5 and 6, great reduction from normal of opsonin for the green-producing streptococcus in fatal influenzal pneumonias. Point of opsonic extinction for normal person 1:60.

On account of the leukopenia in this epidemic of influenza and in the complicating pneumonias, and the frequency of complications, the activity of the leukocytes was also studied. I[2] have previously recorded that the phagocytic activity of the leukocytes is decreased during the leukopenia of measles, and suggested that this might account in some degree for the frequency of secondary infections in this disease.

Suspensions of washed blood containing approximately the same number of polymorphonuclear neutrophils from normal persons and from ten influenzal pneumonia patients were studied. The phagocytic activity of the leukocytes was determined by comparing the number of bacteria ingested under the same conditions by the two sets of leukocytes under the influence of normal serum (cytophagic index). In the case of all patients examined during the leukopenia, the polymorphonuclear cells were found to be less actively phagocytic than normal cells, the average being 0.1, as compared with the normal standard 1.00. In two patients who recovered, the leukocytes became actively phagocytic as their number returned to normal. This decreased leukocytic activity was not specific, the same change occurring with *Bacillus influenzae, Micrococcus catarrhalis* and *Streptococcus hemolyticus*.

CONCLUSIONS

1. Specific opsonins for the green-producing streptococcus isolated from influenza patients developed during the course of the disease.

2. A specific decrease in opsonins for the organism occurs in the pneumonia following influenza. This lowered opsonic power persists unless the patient recovers, when it returns to or may rise considerably above normal.

The changes in opsonic power in influenza and influenzal pneumonia are specific for the green-producing streptococcus, no fluctuations being observed with *Bacillus influenzae, Micrococcus catarrhalis* or *Streptococcus hemolyticus*.

3. These experiments would indicate that the green-producing streptococcus is of some significance in influenza and the complicating pneumonia.

4. Accompanying the leukopenia of influenza occurs a nonspecific decrease in the phagocytic activity of the leukocytes. This decreased activity continues unless the patient recovers, in which case the leukocytes become normally active with the increase in number.

5. It is suggested that the leukopenia and the diminution of the phagocytic activity of the leukocytes in influenza may account in some degree for the severity and frequency of secondary infections in this disease. It is possible that convalescent serum or immune horse serum may be of value in promoting leukocytosis and also in increasing the antibody content of the serum.

Vaccination Against Pneumonia.—The experiments of the Army Medical Corps with vaccination against pneumonia due to the pneumococcus, Types I, II and III, in two of the Army camps have had so much apparent success that a memorandum has been issued to officers, enlisted men, and employees of the War Department, announcing that this prophylactic vaccination is available to all who desire it. At Camp Upton during a period of ten weeks, no cases of pneumonia due to the types of pneumococcus mentioned, occurred among vaccinated troops, and pneumonia due to other organisms was only one tenth as high among vaccinated as among the unvaccinated although previous to vaccination the pneumonia had occurred equally in the two groups. The vaccine employed is a lipovaccine. It is given in a single injection, containing pneumococci, Types I, II and III. Reactions from injections, etc., are, as a rule, less pronounced than after the use of antityphoid vaccination. The vaccination is not intended to cure those who are ill with pneumonia, and it is not advised for persons who are suffering from acute colds or fever.

EPIDEMIC OF BRONCHOPNEUMONIA AT CAMP GRANT, ILL.

PRELIMINARY BACTERIOLOGIC REPORT *

EDWIN F. HIRSCH, M.D. (Chicago)
Captain, M. C., U. S. Army
AND
MARION McKINNEY
Chief Technician
CAMP GRANT, ROCKFORD, ILL.

Sept. 21, 1918, an epidemic disease characterized by a sore or dry throat, cough, fever, general prostration, and in a certain number of patients by a rapidly progressing pneumonia, broke out at Camp Grant. While the date September 21 is given as the day of onset during which fifty-six patients were admitted to the base hospital, there had been about fifteen or twenty patients admitted during the three or four days immediately preceding with symptoms identical, and had been considered to have "influenza."

The rapidity with which the disease spread can be appreciated best by reviewing the number of hospital admissions on the days succeeding the onset of the epidemic, indicated in Chart 1. The first death occurred on the third day, and the postmortem examination confirmed the clinical diagnosis of bronchopneumonia. The number of deaths on the subsequent days of the epidemic are indicated in Chart 2. Practically all deaths followed a clinical diagnosis of pneumonia, a diagnosis largely supported by postmortem examinations.

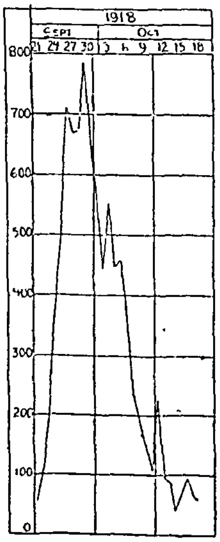

Chart 1. — Admission rate: September 21, 56; 22, 108; 23, 193; 24, 369; 25, 491; 26, 711; 27, 670; 28, 671; 29, 788; 30, 689; October 1, 567; 2, 440; 3, 566; 4, 445; 5, 459; 6, 375; 7, 235; 8, 197; 9, 155; 10, 118; 11, 229; 12, 98; 13, 87; 14, 40; 15, 64; 16, 95; 17, 67; 18, 54.

The arrival in the hospital of a large number of patients with symptoms referable to infection of the respiratory passages suggested at once that the possible or even highly probable portal of entry of the disease-producing organism or organisms was through the nasopharynx, and that a bacteriologic examination of these tissues would demonstrate the variety of bacteria as well as the predominating type of organism, if there be such. Following this as a reasonable basis for investigation, throat cultures were taken on Loeffler's medium from the posterior pharynx of the first 300 hospital admissions and examined after twenty-four hours' incubation. The predominating organisms growing on this medium were gram-positive, usually diplococci as such or in short chains. Following this, 159 throat cultures were taken on blood agar plates in order to differentiate the gram-positive organisms, as well as to favor the growth of the influenza bacillus whenever it would be present. Many of these plates were pure cultures of fine green colonies containing gram-positive diplococci as such or in short chains, frequently lancet shaped. In all throat cultures the occurrence of the influenza bacillus was only occasional, never in pure culture, and, when found, always with a predominating number of diplococci with tinctorial, morphologic and cultural characteristics as mentioned above. A few colonies of hemolytic streptococci were noted in twenty of the 159 blood agar plates, nonhemolytic in not more than twelve.

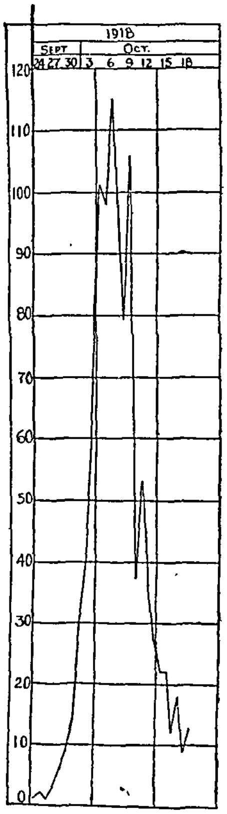

Chart 2.—Death rate: September 24, 1; 25, 2; 26, 1; 27, 3; 28, 6; 29, 9; 30, 14; October 1, 31; 2, 43; 3, 76; 4, 101; 5, 98; 6, 115; 7, 98; 8, 79; 9, 106; 10, 37; 11, 53; 12, 36; 13, 27; 14, 22; 15, 22; 16, 12; 17, 18; 18, 9; 19, 13.

Approximately 200 postmortem examinations were made during the epidemic, and there was found regularly an extensive irregular consolidation of the lungs. The gross appearance of these lungs was striking in that they appeared voluminous and dark red, with much blood and edema. On the pleural surfaces there was little fibrin. The bronchi contained a thin gray or brown fluid and were lined by a red mucous membrane. During the decline of the epidemic, gray nodular consolidations were found, and complications and sequelae of a pneumonia, such as huge serofibrinous pleuritis, empyema, acute serofibrinous and acute suppurative pericarditis, all of these contributing no small part in continuing the mortality.

Cultures on blood agar plates and direct smears on glass slides were made from the exudate of the consolidated lungs at all postmortem examinations. The surface streaks of the blood agar plates frequently were purely fine green colonies containing gram-positive, lancet-shaped diplococci. Organisms resembling the influenza bacillus were rarely found, and never in pure culture.

Heart's blood was taken at each necropsy and cultivated. In a large number the gram-positive organism described above was isolated in pure culture. Blood cultures were made on ninety patients in the hospital and forty-five of them were positive, a gram-positive diplococcus being isolated in pure strain without exception.

Spinal fluid removed at the postmortem examinations and from patients in the hospital has yielded this organism frequently, and it has been cultivated in pure strains from the exudate in the middle ears, from the frontal, maxillary and ethmoidal sinuses. In none of the sinus infections of the head has the influenza bacillus been observed either in direct smears of the exudate or in the blood agar plate cultures.

A large number of strains of this organism have been isolated from the lungs and the heart's blood at the postmortem examinations, and from the circulating blood stream of patients in the hospital. Table 1 contains certain cultural, morphologic and virulence properties for a few from the heart's blood, and Table 2 the same for those isolated from the blood stream of patients in the hospital, while Table 3 lists a few from the lungs. These tables indicate that the gram-positive diplococcus recovered from these fluids and tissues has all the morphologic and cultural characteristics of

---

*From the Laboratory of the Base Hospital.

a pneumococcus, at least so far as modern standards of identification permit. They further detail experiments demonstrating the exceedingly great virulence these strains possess for susceptible laboratory animals. A guinea-pig of 328 gm. weight was dead ten hours after an intraperitoneal injection of half the twenty-four-hour growth on a blood agar slant of one of the strains isolated from the heart's blood. The virulence of these strains exceeds by far that known for pneumococci usually associated with disease, and while the organisms meet all the morphologic and cultural requirements of a pneumococcus, this difference in virulence makes them distinctive.

TABLE 1.—HEART'S BLOOD CULTURES, POSTMORTEM

Culture	Inulin Fermentation	Capsule		Bile Solubility	Amount of 1-24 Hr. Blood Agar Slant Injected into W. Mouse	Dose Fatal in Hours	Type	Organism Recovered Pure from Mouse Heart's Blood
		On Blood Agar	In h. b. of Mouse					
1024	+	—	+	+	0.0231	38	II	+
1029	+	—	+	+	0.0231	26	II	+
1030	+	—	+	+	0.0231	31	II	+
1031	+	+	+	+	0.0231	25	II	+
1032	+	—	+	+	0.0231	25	IV	+
1033	—	—	+	+	0.0231	25	IV	+
1034	+	+	+	+	0.0231	25	IV	+
1035	+	+	+	+	0.0231	31	II	+
1037	—	—	+	+	0.0231	27	II	+

1041	—	+	+	+	0.0231	30	IV	+
1050	+	—	+	+	0.0231	28	II	+
1053	+	—	+	+	0.0231	43	II	+
1056	+	—	+	+	0.0231	21	IV	+

To control these investigations, throat cultures were taken from fifty of the German prisoners confined at Camp Grant. This group of men has escaped entirely the infection, although they have been in the camp since last spring. Colonies of pneumococci were found in twenty of these cultures and isolated in pure culture. White mice were inoculated with half the growth of these organisms on blood agar slants after twenty-four hours' incubation without the slightest effect on these animals.

655	+	—	+	+	0.0231	14	II	+
660	+	—	+	+	0.0231	30	IV	+
663	+	—	+	+	0.0231	16	II	+
664	+	—	+	+	0.0231	22	IV	+
665	—	—	+	+	0.0231	16	II	+
666	—	—	+	+	0.0231	36	II	+

CONCLUSIONS

1. The epidemic of bronchopneumonia at Camp Grant is due to infection by a virulent strain of pneumococcus.

2. The virulence of this organism exceeds greatly that of strains usually identified in pneumonia.

3. This virulence is such as to explain the epidemic of bronchopneumonia.

4. *Bacillus influenzae* played no rôle in the epidemic at Camp Grant.

CLINICAL OBSERVATIONS ON INFLUENZA

BERNARD FANTUS, M.S., M.D.
Associate Professor of Therapeutics, Rush Medical College
CHICAGO

The epidemic, or rather pandemic, of influenza through which Chicago has just passed has afforded me an opportunity of making observations that it might be of interest to record, as they were made in family practice, which is not so well represented in medical literature as is that of the hospital, even though the vast bulk of the work of the medical profession lies in the former field rather than in the latter.

One of the startling features of the pandemic was its sudden flaring up and its equally sudden decline, reminding one of a flame consuming highly combustible material, which died down as soon as the supply of the material was exhausted. There is every reason to believe that, within a few weeks of its onset, the infection was universally present in the nose and throat of the people, disseminated by mouth spray given off on talking by innumerable carriers and, in addition, by the coughing and sneezing of the sick. Susceptibility was very general, though it varied greatly in degree. Among those who escaped well marked sickness there are few who could not recall having had an occluded or running nose, or a raw feeling in the throat, or a cough, or aches and pains, at some time during the period of the prevalence of the disease, these probably representing the price such persons paid for their immunization. That blood relationship had something to do with susceptibility was shown by the fact that, in some families, every member developed the disease in well marked form, while in others there was not one definite case, though exposure to the infection had taken place. The very old and the very young showed themselves, on the whole, less susceptible.

In view of this universal prevalence of the infection, quarantine was necessarily useless. During this pandemic, wearing of face masks had no greater prophylactic effect than the liberal consumption of whisky that was indulged in by some for this purpose, or the traditional camphor bags that were found hanging about the necks of so many children sick with influenza. That face masks were useless in protecting one against the infection was shown by the fact that nurses, who of all people were especially given to wearing them, were notoriously prone to become victims of the infection. This is easily understood when we realize that the conjunctiva is continuous with the respiratory mucous membrane and that the eye, unless especially protected, is particularly exposed to bombardment by minute particles in the air. Of course, face masks are useful to protect others against infection by the mouth spray of the wearer.

The symptomatology of the disease was quite multiform. Thus, there were cases that merely showed fever without aches and pains, and others in which there were aches and pains without fever, though generally both were present. Profuse sweating occurred in most cases, increased undoubtedly by the medication employed. The majority of patients coughed, some coughed and vomited, and some vomited and did not cough. The nose was not as frequently affected as were the bronchial tubes. When it was involved, there was a marked tendency to nosebleed. The throat was rarely complained of. Its examination merely revealed hyperemia, and only exceptionally follicular exudate. A few cases of dysenteriform disturbance were encountered. Prostration was generally out of proportion to the height and duration of the fever.

The average duration of the disease in uncomplicated cases was about three days. There was, however, quite a tendency to the occurrence of a relapse, increased, it seemed, by getting out of bed prematurely. The relapse was in some cases more severe than the primary attack, and in others less severe.

Bronchopneumonia was the most important and most serious complication. In every case of pneumonia that I observed in this epidemic, its occurrence was apparently due either to inability or unwillingness, on the part of the patient, to stay in bed long enough or thoroughly enough; or to physiologic handicaps, such as pregnancy, organic heart disease, chronic bronchitis, infancy or old age; or, most especially, to these two influences combined. Over and over again, this was the story: The patient had an ordinary attack of influenza, during which he did not stay in bed continuously. He then felt a little better, got up, and was taken sick again—this time with severe symptoms—and he soon displayed the phenomena of bronchopneumonia. On the other hand, patients who from the beginning of their sickness were kept in bed continuously, and who staid in bed until they had been perfectly well for two or three days, seemed to be quite immune from this complication. If thorough bed treatment of the attack of influenza actually prevents bronchopneumonia, as is my belief, then we must consider this treatment of life-saving importance. How bed treatment might prevent pneumonia, as well as lessen the tendency to relapse, can be understood when we think of an attack of influenza as a state during which the victim of the infection acquires immunity against the organisms that are attempting to invade his system. We have abundant evidence that warmth favors the development of immunity, and that chilling antagonizes it. A patient who is kept in bed at a uniform temperature is therefore in a favorable condition to triumph over the enemy within him. Chilling, on the other hand, weakens the defenses and turns the tide of battle against the patient. Sweaty skins and wet garments predispose to chilling. Thus it is easy to see why the freely perspiring influenza patient must be particularly susceptible to chilling. Especially critical is the period when the patient's temperature is just falling to, or below, the normal. He is then commencing to feel fairly well, and sees no reason for staying in bed. With skin and garments wet with perspiration, he gets out of bed, but soon returns, chilly and miserable, having lost the immunity that was just becoming established. A relapse or an attack of bronchopneumonia is the result.

The time the patient should remain in bed might be placed, for mild cases, at from two to three days, counted from the time the patient has commenced to feel perfectly well for a whole day. For severe cases, and in handicapped patients, or when fine crepitant râles continue to be heard in the chest, the time taken for full establishment of convalescence should be considerably increased.

As it is important to protect the patient against chilling, use of the bed pan and of the urinal must be insisted on. This also prevents the fainting on going into the toilet room that occurred in quite a number of cases. It is no less important to keep the patient's garments and bedclothing dry. The danger of wet clothing is best appreciated when it is realized that a person wrapped in wet fabric loses heat faster than the same body would if it were naked. To keep these profusely perspiring patients dry is quite a task, which should, however, be faithfully carried out by the nurse, who, on removing the wet garments, should rub the patient dry with a warm towel and apply warm, dry clothing, all this being done under covers. The proposition of keeping the patient warm must not be carried out to the extent of keeping the patient hot. The temperature of the sick room should not exceed 70 F. Nor does this proposition militate against free ventilation, provided this is carried out so as to admit fresh air liberally into the room without exposing its occupants to the danger of chilling. For most of these cases, good nursing was more important, as well as more difficult to secure, than good doctoring. This pandemic occurring at a time when there was such great scarcity of trained nurses, on account of the war, brought home to us how necessary it is for every woman—and every man—to be at least somewhat skilled in nursing the sick.

In view of the absence of specific treatment, the therapy of this disease had to be symptomatic. This form of therapy—often disdainfully characterized as "merely symptomatic"—represents, in my view, the very acme of the medical art. Perhaps, if we would instead use the term "functional therapy," as has been suggested, its significance and importance would be better appreciated. It is our duty and privilege to take care of the derangements of the patient's functions while his system is fighting the infection. Since these derangements were of most varied character and intensity, such a thing as a routine treatment of influenza is obviously an absurdity.

The symptom that perhaps attracted most therapeutic attention, and probably least deserved it, was the fever. This was rarely high enough to be of detriment to the patient. When it became too high—exceeded, let us say, 104 F.—it was easy to reduce it by hydrotherapy or by antipyretic medication. On the other hand, a proper object of therapeutic attack were the pains and aches to which so many of these patients were subject. It was their analgesic, rather than their antipyretic action, that rendered various coal-tar derivatives so useful in this condition. It made very little difference whether acetylsalicylic acid or other salicylate, acetphenetidin, antipyrin or pyramidon were selected, provided the proper dose was chosen, namely, the smallest possible dose adequate to produce the desired result. I have seen as little as 0.12 gm. of acetphenetidin or of pyramidon, when given every hour, followed within a few hours by complete relief of the discomforts against which they were administered. The chief disadvantage of all these bodies is their great sudorific action. This at times made the patients more uncomfortable than the aches against which they were used. Hence, when great pain was complained of, and its antitussic action did not render it contraindicated, I have added an opiate—generally codein phosphate, 0.03 gm., to each dose of pyramidon—rather than to increase the dose of the coal-tar analgesic. It is a somewhat disagreeable thing to reflect on that this treatment might make the patient feel so comfortable that, considering himself well before he really is, he may interrupt his bed treatment prematurely and thus invite occurrence of relapse or even of pneumonia.

The proper management of the cough is probably of fundamental importance. If retention of secretion and clogging up of bronchioles favors the development of bronchopneumonia, as it is only reasonable to believe, then favoring expectoration may save life. It has been my good fortune to come across a number of patients in whom, from the rapid and distressed breathing, the almost nonproductive cough, and the innumerable fine râles in the chest, one feared the onset of pneumonia, that cleared up phenomenally, within a couple of days, under the influence of iodid coupled with the liberal ingestion of fluid. In milder cases, I have used, as expectorant, ammonium chlorid in doses of 0.3 gm. prescribed with a flavoring syrup vehicle and taken in half a tumblerful of water, every two hours. But, when the more serious nature of the case demanded a more drastic action, or when the patient obtained no relief from the ammonium chlorid, I have nearly always succeeded in securing a satisfactory result by the addition of 0.12 gm. of sodium iodid to each dose of ammonium chlorid, given in cases in which prompt action seemed urgent every hour, and later, every two to four hours. The interval between the doses is increased as expectoration or nasal discharge become freely established. Reasoning and clinical observation have led me to believe that any expectorant given for the purpose of loosening secretion is likely to be disappointing unless its administration is accompanied by the liberal ingestion of fluid. Hence I have urged the ingestion of a tumblerful of fluid every hour, while the patient is awake, having the patient take a tumblerful of milk or other nutritious fluid every two hours, and a glassful of lemonade, grape juice and water, seltzer water, or other drink every two hours, alternating with the milk. When the secretion has become profuse, an aromatic expectorant like creosote carbonate would seem to be indicated. However, in these cases I have found this agent unsatisfactory. In a number of instances, discontinuance of the iodid and use of creosote carbonate in 0.3 gm. doses every four hours was followed by prompt aggravation of the cough and increase in the number of râles heard in the chest, as well as the reappearance of fever. I therefore now reduce the daily dosage of iodid very gradually instead of stopping it abruptly, and have not employed creosote carbonate of late, even when the expectoration has seemed excessive. I believe that the prescribing of an opiate, whether by itself or in complex cough syrups, is pernicious practice, a direct invitation to the onset of bronchopneumonia. An exceptional case may be found now and then, in which a patient with a chest free from physical findings is kept from sleep by a useless, absolutely nonproductive cough. In such a case, a sufficient dose of codein, 0.03 gm. every hour at bedtime for a few doses, secures a good night's rest; and the ingestion of a dose every four hours during the day maintains comfort. When, however, the cough is at all productive or there are râles in the chest, experience has made me afraid to prescribe opiates in any form or any dose. Even if the opiate is not followed by the development of bronchopneumonia, it will prolong the duration of the trouble, as the harassing cough returns as soon as the opiate is stopped. Should the cough be excessive and interfere with sleep, it is well to try to lessen the nervous excitability by means of bromid, which may be given combined with the iodid.

Insomnia should not be permittted in these patients for more than one night. Since sleep is as important as food for the maintenance of strength, and as we never know at the beginning how long the case may last or how serious it may become, it is, to say the least, prudent to procure sleep for the sufferer. The sleep must not be sufficiently profound or continuous, however, to abolish coughing for many hours. I have found it convenient to carry with me 0.3 gm. barbital tablets and to have the patient who has difficulty in going to sleep take one at bedtime, to be repeated in two hours if he is not yet asleep. As barbital has not proved uniformly successful, I have prescribed with more complete satisfaction in those cases in which barbital failed, 0.3 gm. of chloral hydrate to be repeated every hour until the patient is asleep. Of course, the chloral could not be used in patients with enfeebled circulation.

A tendency to vomiting on slight provocation was so generally present, especially in children and young women, that it was found wise to limit the patient to liquid diet. Eating crackers or an apple has precipitated an attack of emesis. Medicine was also likely to do this, especially the administration of ammonium chlorid. Hence it is well to start this medication cautiously in those predisposed to emesis, by giving at first one-fourth and later one-half the desired dose and not going up to the full dose until one feels confident that it is likely to be tolerated. With some patients, vomiting was a prominent and distressing symptom. In such cases, twenty-four hours of complete rest to the stomach, even to the extent of limiting the ingestion of water to teaspoonful doses every fifteen minutes and withholding all medicine, usually controlled the difficulty. To prevent dehydration of the system and the development of acidosis, as well as to favor expectoration, retention enemas of 250 c.c., or of as much as the patient could hold, of physiologic sodium chlorid solution with sodium bicarbonate, two teaspoonfuls to the quart, were used from every four to eight hours, the shorter intervals being employed when the amount that could be retained was rather small.

It would consume too much space to describe in detail all the other measures that were found useful: such as prolonged irrigation of the auditory meatus with hot water followed by hot glycerin for earache, the use of menthol for the rhinitis, or of the potassium chlorate-ferric chlorid gargle for sore throat, when disturbance of these parts was prominent; strapping the lower border of the ribs with adhesive plaster for pain and soreness due to strain from coughing, and the application of the ice bag for excessive headache, or mustard poultices to especially sore areas elsewhere. The employment of cathartics was, of course, quite generally required. Solution of magnesium citrate was so popular for this purpose that druggists could hardly put it up fast enough during the pandemic to keep ahead of the demand.

I am fully aware of the fact that the great shortcoming of such reports as this one is its lack of numerical data and hence of definiteness, and the consequent difficulty of arriving at scientific conclusions. Even though the observations laid down were made in more than a thousand cases of influenza, many of these were seen only once. Hence it is impossible to be certain of the subsequent course in a considerable number of these cases. Some of these patients may subsequently have developed pneumonia and called another physician. Among those treated from the very beginning, whose subsequent course was known, bronchopneumonia occurred in four cases.

One patient was a pregnant woman who did not stay in bed during the first febrile period, because for a part of the time she had to take care of herself and of a sick baby. She recovered.

One patient, a young foreigner, came to my office with a temperature of 103 F. When he arrived home with instructions that he must go to bed and stay there, his wife turned him out of the house, saying that she had to look out for herself and her children. He stayed without care in a rooming house for three days, and when I saw him again he had a violent hemorrhagic bronchopneumonia from which he died.

A young man with valvular heart disease, who was taken care of by his mother and who refused to stay in bed for evacuation of urine and feces, developed pneumonia and died from it within five days of the beginning of the disease.

An old woman, who probably stayed in bed from the commencement of her illness, developed an extensive bronchopneumonia involvement from which she died after ten days.

In nearly every instance of about twenty-five cases of bronchopneumonia seen for the first time after the establishment of this complication, there was a history of incomplete bed treatment; and, in some, considerable evidence that the physician previously in charge had used an opiate.

SUMMARY

Bronchopneumonia, the great cause of death from influenza, is probably in a considerable proportion of cases a preventable complication.

The prevention of bronchopneumonia rests chiefly on the enforcement of sufficiently thorough and prolonged rest in bed, and the favoring of free expectoration by the copious ingestion of fluid and perhaps the use of iodid and the avoidance of opiates.

ACUTE VEGETATIVE ENDOCARDITIS WITH MULTIPLE SECONDARY FOCI OF INVOLVEMENT

DUE TO MICROCOCCUS PHARYNGITIDIS-SICCAE[*]

OSCAR T. SCHULTZ, M.D. (Chicago)
Captain, M. C., U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

Medical work in the armies of this country and of European countries has brought to light, not only new diseases, like trench fever, but also manifestations of infectious agents previously infrequent in civil life. As examples of the latter may be mentioned the increasingly great importance of the hemolytic streptococcus as a cause of pneumonia and of empyema in this country during the past winter, and the causation of bacteremia and other conditions by *M. catarrhalis,* previously considered almost if not quite harmless, as reported by British army surgeons. Of a similar nature, that is, a fatal infection by an organism ordinarily a harmless parasite, is the case reported herewith. Terminal infection by *B. coli* and other normally nonpathogenic bacteria occurs frequently enough in individuals whose resistance has been weakened by other disease. In the case reported the organism concerned has probably never before caused an infection of the kind described, and the infection occurred in an individual who was doing full military duty and who was not weakened by any other disease condition.

REPORT OF CASE

Clinical Course.—A private, white, aged 25, a member of the Headquarters Company of the Military Police was admitted to the base hospital, Camp Jackson, July 25, 1918. The family history was negative. He had had pneumonia in 1913; otherwise the previous history was negative. Particularly is it to be noted that he had never had rheumatism. July 17, while in the city of Columbia, he complained of headache, fever, and pains all over the body. He remained in the barracks until July 22, when he reported for duty. July 24, he was drenched in a storm. He reported at sick call next morning, complaining of pains and aches all over the body, and was sent to the base hospital. On admission the lungs and abdomen were negative. Old herpes labialis was present. The heart was not enlarged, the sounds were of good quality, and a loud systolic murmur was present at the apex. On the four days following admission the clinical record makes no note of anything of importance except fever. July 30, petechial spots were noted on the abdomen. July 31, the following notes were made by Major W. W. Herrick, Chief of the Medical Service:

> "Mentally alert. Does not look very toxic. Heart: Apex difficult to locate, apparently in nipple line; right border 1½ inches from midsternum; at apex a loud, rough, blowing systolic murmur, heard in the left axilla and also all over the precordium. Lungs clear. Spleen felt one-half inch below ribs. . . . Profuse petechial eruption over trunk and extremities. A few on the conjunctiva and one on the hard palate."

The diagnosis at this time was septic endocarditis, probably streptococcic. August 1, there was shortness of breath and cyanosis of the finger tips. August 2, the petechial rash was very general over the trunk, and the systolic murmur at the apex was harsher and louder than before. On this day he became irrational. August 3, the pulse was weak, rapid and thready, and the patient was irrational and unconscious. He died at 4:15 a. m., August 4.

Repeated examinations of the blood for malaria were negative. Blood cultures were made, July 30 and August 2. Each of these gave a pure culture of a gram-negative diplococcus that was not agglutinated by polyvalent antimeningococcus serum. August 1, the urine contained a few pus cells and red blood corpuscles. Examination of spinal fluid removed, August 2 showed a trace of globulin, pus cells, but no organisms. The white blood count is given in Table 1.

---

TABLE 1.—WHITE BLOOD COUNT

Date	Total	Small Mononuclears Per Cent.	Large Mononuclears Per Cent.	Polymorphonuclears Per Cent.
July 26	18,000	7	3	90
July 27	16,000	10	2	88
July 29	20,600	14	..	86
Aug. 1	29,200	9	..	91

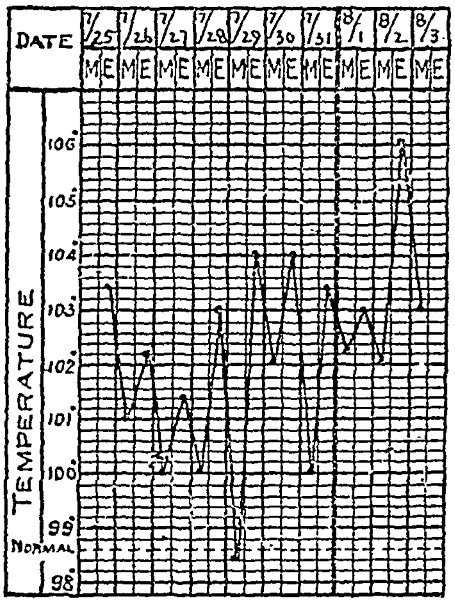
The course of the temperature is shown by the chart.

Necropsy.—The examination was made six hours after death.

External Examination: In the skin of the arms, chest, abdomen and neck were a number of sharply defined, bright red petechiae from 1 to 2 mm. in diameter. These were most numerous in the skin of the neck.

Internal Examination: The peritoneal, pleural and pericardial cavities were free of excess fluid. In the parietal peritoneum were a number of petechiae, of the size and appearance of those of the skin. A few similar lesions were present in both parietal pleurae, and they were more numerous in the parietal pericardium, especially that over the diaphragm, than in the pleurae or peritoneum.

Heart: On the anterior surface of the heart was an irregular milky spot. The right auricle and ventricle were distended. The apex extended to one finger's breadth beyond the left nipple line. The tricuspid and pulmonic valves were normal. On each segment of the mitral valve, where the segments come together anteriorly, was a mass of pale, wartlike or papillomatous vegetations, each mass measuring about 1 cm. in diameter. Some of the wartlike outgrowths making up these masses were attached by very slender peduncles. On the chordae of the posterior segment, beneath the free margin of the latter, was a third group of similar nodular vegetations. The vegetations were rather soft. The aortic valves and the root of the aorta were normal. Over the apex of the left ventricle, the tissue appeared congested through the epicardium. On section through this region, the heart wall contained two poorly defined, irregularly outlined areas, lying very close together and each about 1 cm. in greatest diameter, in which the heart muscle was pale and opaque. The opaque muscle was surrounded by a narrow zone of deeply congested tissue.



Course of the temperature.

Spleen: This was about three times the normal size. The capsule was thin, smooth and glistening. Through the capsule the tissue of the convex surface near the upper pole had a mottled appearance. On section this region was poorly defined, occupied about one-fourth the long axis of the spleen, and the tissue was paler and cloudier than the rest of the tissue, which was grayish red. At the middle of the long axis of the spleen was a second small area similar to that described.

Liver: The size, consistency and external surface were normal. Scattered about on the cut surface after section were a number of opaque, yellowish spots, from 0.5 to 1 mm. in diameter.

Kidneys: These were slightly increased in size. The capsule of each was thin and was easily removed. After the capsule was removed the surface of each kidney showed numerous dark red areas from 0.5 to 2 mm. in diameter. At the anterior surface of the upper pole of the left kidney was an irregularly shaped area 5 cm. in greatest diameter, which was centrally pale and peripherally dark red. The middle of the convex border of the left kidney showed a similar area 1.5 cm. in greatest diameter on the surface, and the upper pole of the right kidney contained a similar lesion. On section the small, deep red areas noted on the surface extended downward through the cortex as narrow, deep red wedges. The larger areas were centrally opaque, surrounded by intensely congested tissue, and extended entirely through the cortex. The cortical tissue between the lesions was opaque and cloudy. The pelves and ureters were normal.

Gastro-Intestinal Tract: The intestine, in situ, showed through the peritoneum a number of dark red, fairly sharply outlined, round areas from 0.5 to 1.5 cm. in diameter. In the intestine after removal were found large numbers of these areas, and they were present throughout the intestine from the duodenum to the sigmoid. They tended to be arranged in groups of from two to four or five. Some had shotlike, firm, slightly raised, opaque, grayish centers about 0.5 mm. in diameter. Except for these lesions the gastro-intestinal tract appeared normal.

Microscopic Examination.—Lung: In areas which usually comprise several lobules the tissue was consolidated. At the center of such areas was a bronchus whose epithelium was partly desquamated and whose lumen was filled with pus cells. The alveoli surrounding the bronchus were filled with polymorphonuclear leukocytes, and the septal capillaries were distended with blood. Farther out, the air spaces were filled with red corpuscles. No fibrin was present. Between the consolidated areas the lung tissue was normal.

Heart: In sections from the margins of the infarcted areas of the left ventricle, the muscle cells nearest the lesion were granular and necrotic. Their nuclei were partly pyknotic and partly fragmented. Farther away from the infarct the muscle fibers were swollen and faintly stained. The stroma between the muscle tissue was edematous. One section contained a large vein, cut in cross-section, which was markedly involved. At one point the intima was replaced by a nodular area composed of necrotic connective tissue infiltrated by polymorphonuclear leukocytes. At another point the wall, in an area comprising about one-fourth the circumference of the vessel, was completely necrotic throughout its entire thickness. The tissue surrounding the vessel was necrotic, and was densely infiltrated by polymorphonuclear leukocytes.

Mitral Valve: The tissue of the valve was edematous and contained young connective tissue nuclei, together with a few lymphocytes. Just beneath the vegetation the tissue was partly necrotic and was densely infiltrated by polymorphonuclear leukocytes, the involvement extending through the thickness of the valve into the muscle tissue. On the free surface of the valve the vegetation was attached by a broad base. It was composed almost wholly of irregularly shaped masses of bacteria, which gave to the vegetation under low magnification a cauliflower-like appearance. Between the masses there was structureless, granular, eosin stained material which did not take the Weigert fibrin stain and which contained a few polymorphonuclear leukocytes. On the free surface of the vegetation was a thin layer of similar material which contained red corpuscles. In sections stained by the Gram-Weigert method the bacteria were unstained, with the exception of a few coccus-like bodies in a few of the colonies at the upper part of the vegetation. In sections stained with methylene blue the bacteria were stained, and the masses were composed of cocci arranged in pairs.

Spleen: The infarcted tissue was hemorrhagic, many of its nuclei were fragmented, and it contained polymorphonuclear leukocytes. Numerous polymorphonuclear leukocytes were present in the pulp of an accessory spleen that was present and not infarcted.

Liver: The liver cells were swollen and finely granular. A few contained bile pigment. In a few widely separated, small, sharply defined areas, the liver cells stained faintly, and their cytoplasm was finely vacuolated. A few lymphocytes were present in the interlobular stroma.

Kidney: In the convoluted tubules the epithelium was so swollen as almost to obliterate the lumina. These cells were granular, and a few had lost their nuclei. The glomeruli were swollen, and their capillary loops were indistinct. In an occasional glomerulus one or more loops were granular, necrotic and deeply eosin stained. In some glomeruli the capsule was distended, and the space contained granular material. Many of the tubules in the medulla contained free red corpuscles. The tissue of the larger infarcts was completely necrotic. Peripherally the necrotic tissue was richly infiltrated by polymorphonuclear leukocytes. In the uninfarcted tissue, small, sharply defined collections of pus cells were present. At the center of some of these abscesses a small blood vessel filled with polymorphonuclear leukocytes could be seen. Situated at the side of one vessel was a larger abscess, at the center of which was a colony of bacteria that had the same appearance and staining reaction as the colonies in the valve vegetation.

Suprarenal: The stroma of the cortex was edematous. In the medulla of one suprarenal was a small abscess.

Intestine: In a section through one of the lesions of the small intestine, a dense collection of polymorphonuclear leukocytes and lymphocytes was present in the submucosa. The veins of the surrounding tissue were markedly distended, and free blood was present in the submucosa.

Diagnosis.—The pathologic findings were: Acute vegetative mitral endocarditis. Septic infarction of myocardium. Recent infarction of spleen. Multiple hemorrhagic septic infarcts and multiple white infarcts of both kidneys. Multiple hemorrhagic septic infarcts of intestine. Multiple petechiae of the skin, pericardium, pleura and peritoneum. Cloudy swelling of the myocardium, liver and kidneys. Multiple focal necroses of the liver. Purulent bronchitis and bronchopneumonia. Abscess of the suprarenal medulla. Macula albida of the heart.

Bacteriology.—Blood culture on two occasions during life gave each time a pure culture of a gram-negative coccus which was not agglutinated by polyvalent antimeningococcus serum. At necropsy, cultures were taken from the heart's blood and spleen. Gram-negative diplococci were present in smears from both situations, but the cultures remained sterile, probably because of the use of old mediums. One of the mitral valve vegetations was removed, washed thoroughly in sterile salt solution, ground in a mortar with a small quantity of sterile saline, and a loopful spread on a blood agar plate. Numerous colonies, all of the same organisms, developed. These, at the end of twenty-four hours, were from 0.5 to 2 mm. in diameter; they were slightly irregular in outline but had smooth borders. They were raised, glistening and grayish, with a flattened surface. The colonies were dry and came off in scalelike masses. No pigment was formed, even after prolonged growth. The organism of these colonies was a gram-negative coccus, occurring singly and in pairs, which showed some variation in size. It was identical in morphology and in staining reactions with the coccus obtained in blood culture. A pure culture of the latter and a pure culture from one of the heart vegetation colonies were run through various mediums together, with the results given in Table 2.

TABLE 2.—RESULTS OF CULTURES

	Glucose	Saccharose	Maltose	Inulin	Mannite	Litmus Milk
Culture from blood during life....	Acid	Acid	Acid	0	0	0
Culture from heart valve vegetat'n.	Acid	Acid	Acid	0	0	0

On all solid mediums, the blood culture organism and that from the heart vegetation were characterized by their dry surface growth, which was luxuriant and came off in crustlike flakes. In broth, white, opaque, round masses developed at the surface and on the sides of the tube at the surface. Later the masses fell to the bottom, forming a heavy, cottonlike sediment, the supernatant fluid remaining clear. The bacteriologic diagnosis was *M. pharyngitidis-siccae* from both blood culture and heart vegetation.

COMMENT

In its clinical and pathologic features this case reproduces the conditions usually caused by a virulent streptococcus. A streptococcus could not, however, be cultivated from the blood during life or from the vegetations after death, and no streptococci could be found in the tissues. The only organism cultivated during life and from the necropsy was the gram-negative coccus described, and the blood culture organism and that from the vegetations were identical in every respect. Furthermore, the vegetations were made up of gram-negative cocci. The conclusion which it would appear necessary to draw is that this organism was the causative agent of the infection. Morphologically and culturally the coccus had the characteristics of *M. pharyngitidis-siccae*. Meningococcus and gonococcus, which would be more apt to produce the lesions found, can certainly be excluded. It was at first thought that the organism might be *M. catarrhalis*, but the sugar reactions excluded this also.

The beginning of an infection by such a normal, harmless inhabitant of the throat is difficult to explain. That such an organism should enter the blood stream directly and cause an acute endocarditis and a fatal infection appears improbable. The lungs were the seat of an acute purulent bronchitis with bronchopneumonia. This lesion, from its bronchial and peribronchial distribution, was apparently not hematogenous in origin, as were the lesions of the kidney, intestine, skin and serous membranes. The bronchopneumonia escaped detection during the course of the disease, none of the progress notes of the case indicating the presence of this condition. Although the clinical record states that on admission the lungs were clear, it is possible that the lesion may have been present at this time and may have escaped detection, since the islands of lung tissue involved were small. It would appear most probable, therefore, that the beginning of the infection was a bronchitis with bronchopneumonia, and that from the involved lung tissue the blood stream became invaded. With localization of the cocci on the mitral valves, the further course of the infection followed logically enough.

SUMMARY

A case of acute malignant vegetative mitral endocarditis in its clinical course and in its pathology simulated an endocarditis due to hemolytic streptococcus.

The causative organism was a gram-negative diplococcus, which culturally was *M. pharyngitidis-siccae*, ordinarily a nonpathogenic inhabitant of the throat.

The organism was obtained in pure culture from the blood on two occasions before death, and from the heart valve vegetations after death.

The inception of the infection was probably an acute purulent bronchitis with bronchopneumonia.

Low Blood Pressure and Oxygen Supply.—If hemorrhage complicates a low blood pressure, the critical level is higher than if no hemorrhage has occurred; thus, if an animal has lost 20 per cent. of its blood volume, the mean arterial pressure can not be lowered to 80 mm. without indications of an inadequate oxygen supply to the tissues.—*Review of War Surgery and Medicine.*

SATURDAY, NOVEMBER 23, 1918

WAR GASES AND CHEMICAL WARFARE

The effective use of gases in warfare dates from the spring of 1915, when the Germans first used this hideous weapon on Canadian troops on the western front in France. The idea of the employment of poisonous gases against an enemy had been proposed to the British War Office many years ago, but the decision was reached, in accord with present-day considerations of humane procedure, that it should not be adopted.[1] The Teutonic return to barbaric methods compelled the Allies to adopt retaliatory measures; as a result, with hundreds of American as well as foreign chemists engaged in the chemical warfare service, the German plan of gas attack proved to be a veritable boomerang.

The first gas to be used against the forces of the Allied countries was the poisonous chlorin, which was released from cylinders in the front line of trenches. The gas cloud became a weapon by being rolled along the ground by the wind. For obvious reasons this uncertain mode of gas attack was soon replaced by the use of large shells filled with liquefied products. Several dozens of substances, not all of which are true gases, have already been employed in chemical warfare, so that few persons realize precisely what may be included in the expression "war gas." Lieut.-Col. Wilder D. Bancroft[2] has lately explained the import of this flexible term. The substance, he states, may be a liquid, a solid, a vapor or a true gas. It must, however, have some striking characteristics: it must be poisonous or produce tears (lacrimation); or it must give rise to nausea, sneezing or blisters, have a foul smell though otherwise harmless, or be a smoke with obscuring powers. Of course, it may have any or all of these properties combined.

Obviously a high degree of toxicity is a desideratum in those substances that are intended to damage the enemy by chemical rather than by mechanical means. Bancroft assures us that nowadays no one would consider as a toxic substance anything that did not kill dogs in thirty minutes at a concentration of 1 mg. per liter. It is effective concentration, he adds, that is overlooked by persons who suggest new gases or methods of using old ones. Lacrimatory substances should be effective at concentrations as low as 0.01 mg. per liter. The best are much better than this.

Gas warfare created entirely new problems for us in America. Means of defense against the new menace were the first to be provided. Foremost here was the production of suitable gas masks to meet each new sort of emergency. Then remedial measures for those afflicted had to be sought in what was practically an unexplored terrain of therapy. Thus there were created divisions of the service to study the pharmacology, pathology and therapeutics of poisonous gases. And our forces were not idle in the search of new weapons in this field. Hence a toxicologic section was organized under the leadership of Professor Loevenhart to test the deadly efficiency of the new discoveries. Such activities as the search for raw materials to produce novel products in enormous quantities, perhaps hundreds of tons, the invention of workable modes of manufacture and devices for loading and shipping shells and other containers, and the provision of protection for the workmen in the industrial plants have engaged the best talent of trained men. Science, recognized at length as a potent force and awakened to a realization of its duty, became rampant for success in outwitting the Hun.

SOME FACTORS IN GASTRIC SECRETION

It is many years since the performance of gastric analysis, made possible by the successful introduction of the stomach tube into clinical diagnostic routine, has become an indispensable feature of medical practice. Strangely enough, the technic of this mode of examination has progressed far more rapidly during the intervening period than has the understanding of the fundamental physiologic functions on which the practice of gastric analysis is really based. Decade after decade has witnessed the collection of such facts as the varying acidities and enzymatic powers of collected specimens of gastric contents, while the problems of secretion, absorption and related factors have awaited more satisfactory solutions than those propounded by the usual textbooks of gastroenterology. The mechanism of the movements of the stomach have been elucidated to a far greater degree, thanks to the introduction of roentgenoscopic methods of investigation, than has the chemical physiology of the secretory phenomena.

The discovery of the existence of secretion-promoting hormones, or secretagogues, has paved the way to a clearer insight into long known facts. Thus it was appreciated even before the pioneer experiences of Pawlow that water is a gastric stimulant. Bergeim,

---

[1] This statement is made on the authority of Prof. J. S. Ames: The Trained Man of Science in War, Science, *Oct. 25, 1918, p. 401.*

[2] Bancroft, W. D.: Chemical Warfare Research, Jour. Indust. and Engin. Chem., 1918, **10**, 785.

Rehfuss and Hawk,[1] who have devoted considerable attention to the response of the human stomach to water, report that in the average normal individual water produces fully as great stimulation as does the familiar Ewald test meal. In explanation of the underlying phenomenon, Pawlow had suggested that the stimulation is due to the prolonged and widespread contact of the water with the gastric mucosa. According to the more recent views of the University of Chicago school of physiologists, to whom, under the leadership of Carlson, so much of our present-day knowledge of the performances of the stomach is due, the older explanation is not tenable. Gastric secretion may occur even when water remains in contact with the mucosa for not more than one and one-half minutes. It seems more likely, therefore, that water washes traces of gastric secretagogues into the intestine, from which they are in turn absorbed so that they can act on the secretory glands by way of the blood; for the existence of a gastrin, or true chemical stimulant to secretion, can no longer be doubted.[2] Furthermore, that the dilution of the blood, as has been suggested, cannot be the controlling factor in promoting gastric secretion by water ingestion, is evident from the added demonstration that stimulation results even when practically no water is absorbed.[3]

The effectiveness of gastrin, preparations of which can be injected at will, in provoking gastric secretion, has made it possible to investigate the debated question of glandular fatigue. In the more careless conversations on clinical topics, one often hears of the importance of resting one or another of the secretory glands. The kidney cells and the cells of the gastric mucosa in particular are popularly supposed to require "rest," despite the undeniable fact that the secretion of urine is quite continuous or uninterrupted, as is the function of the heart or the respiratory center. The essential for their normally continued function is, of course, the orderly balance between destructive and constructive cellular processes, between anabolic and catabolic phases of metabolism, between reception of energy and oxygen and removal of chemical débris. Accordingly, it has been found impossible in the case of the gastric glands likewise to demonstrate a "fatigue" when they are stimulated by water or by gastrin for a period of from sixteen to twenty-six hours—surely a sufficient test. Hence, as to gastric glandular fatigue, says Ivy[3] in speaking of his new experiments at the University of Chicago, it is only reasonable to believe that so long as the normal gastric glands are supplied by the blood with the normal quality and quantity of constituents that form the gastric juice, no fatigue will be observed; but as soon as the blood fails to supply these necessary constituents, a change in the normal character of the gastric juice will occur. Even then, as Ivy adds, it cannot be said that the glands are fatigued; but rather they have only been deprived of the raw products necessary for their normal functioning. It is a somewhat unusual, yet unquestionably helpful point of view to interpret gastric secretory performance from the consideration of the blood supply rather than primarily the cells of the stomach or their innervation.

MEDICAL DEMOBILIZATION

From the present outlook it would appear that in the demobilization of the Army, officers can, if qualified, join the Regular Corps or the Medical Reserve Corps, or they may be honorably discharged. The medical officers of the Army and Navy constitute a splendid body of some 35,000 physicians, well trained and well equipped. It would be a mistake — in fact, almost a crime — to permit these men to be completely detached from the Army and Navy and to be absorbed in civilian life. Hence it is to be hoped that the third group—those requesting honorable discharge —will be comparatively small.

As is well known, the old Medical Reserve Corps was not really an active organization. It consisted of some 1,450 physicians affiliated with the Medical Department of the Army, but practically in name only. The National Defense Act of 1916, in creating the Officers' Reserve Corps, provided that the old Medical Reserve Corps should cease to exist and be replaced by the Medical Section of the newly created Officers' Reserve Corps. The Medical Corps thus created would have been more vital—actually a functionating body, since the act provided for instruction to be given to members of the Reserve Corps for periods of fifteen days each calendar year, and for pay and allowance during the period of instruction. Longer periods than fifteen days could be utilized with the officer's consent. But before the new law went into effect, our country had entered the world war.

Conditions are now radically different from what they were in 1916. We now have a large Medical Corps composed of men who have served in camps of instruction, in cantonments, in the field, in hospitals and on board ships. They do not require training of the character contemplated by the National Defense Act. Undoubtedly, therefore, this act will be modified to meet new conditions. In fact, it is announced that the Secretary of War will shortly present to Congress an outline for such modification. It is hoped that the new legislation will provide a method by which officers who desire to do so can continue an intimate contact with the Army. This is certainly desirable so far as the medical officers are concerned, the great mass of whom made large sacrifices in order to serve their country. They have become interested in army life and methods; they will not be content to be honorably discharged and thereby shelved. Perhaps the feeling is partly sentimental, but largely it is patriotic. Further, the occasion may arise when their services will be useful.

[3] Ivy, A. C.: Contributions to the Physiology of the Stomach, XLVIII, Studies in Water Drinking, Am Jour. Physiol., 1918, **46**, 420.

Undoubtedly the Medical Reserve Corps will be continued. But if it is, it might be desirable so to modify its organization as to provide for two classes of members: In one class would be those men within active military age who are now in the service and who have had sufficient military experience to make further training unnecessary. This group, therefore, would not require active training in the camps each year. In the other class would be those who have not had sufficient training and those newly commissioned. This would mean that the Officers' Reserve Corps would be composed of a trained group and a training group. However, the point we desire to emphasize above all others is: In the demobilization an opportunity should be given every medical man now in the service who is trained and physically qualified to retain some connection with the Army.

WAR EMERGENCY AND MEDICAL EDUCATION

At the time the United States entered the world war and until a few months ago, there were grounds for the belief that the war might extend over an indefinite number of years. That, indeed, was the only safe assumption the government could take in its plans for carrying on the war. Following the extension of the selective service regulations to include practically all men of college age, units of the Students' Army Training Corps were established in the approved colleges of arts and sciences. Later the War Department decided to establish such units also in the well recognized medical schools. Medical students were already enrolled in the Medical Enlisted Reserve Corps and were exempted from the draft, but were now ordered to be inducted into active service in the Students' Army Training Corps. The medical schools began at once to carry out the orders and to provide barracks, mess, drill space, etc. The government was to provide the uniforms, board and tuition of students transferred, and, in addition, to give the students the pay of private soldiers. In only about half of the medical schools, however, had the majority of students been transferred when the armistice was signed and further inductions into the Students' Army Training Corps stopped.

The man-power law extending the requirements of the selective service law was not enacted until August. This made it necessary for the Committee on Education and Special Training to work out the necessarily elaborate plans and carry them into effect in an incredibly short space of time. The medical schools had completed their teaching schedules, and many of them had begun their regular sessions before the program for the transfer of their classes to the Students' Army Training Corps was announced. The deans of the medical schools had, in fact, received no previous intimation regarding the radical nature of the changes finally ordered. The time-consuming routine of changing the students from a civilian to a military status — questionnaires, physical examinations, inductions, waiting in line, etc. — took up most of the students' time which otherwise would have been spent in study. The placing of six hours a week of military training into an already overcrowded schedule added to the confusion, which, in many instances, was further increased by a temporary conflict between the military officer who was supreme and educational officers. For example, drill hours were fixed at the time set for laboratory or clinical courses. Orders through military channels were finally sent to the commanding officers in medical schools where conflicts occurred to make the hours for military drill conform with the teaching schedules. Other difficulties, such as the assignment of students to guard duty, to raking leaves, to kitchen police duties and the like, were also settled by similar orders. Again, the giving up of quiet rooms at their homes or in other private dwellings and the living in barracks, where no provision had been made for study, took away from the students their opportunity for effective work. To cap the climax came the epidemic of influenza, which required the closing of many of the schools. As a consequence, during the time that has elapsed since the opening of the college session, little or no effective teaching has been done in many of the medical schools in which active military training had been established. The difficulty was not due so much to the military training as to the requirement that the students live in barracks and the failure to have the drill hours fit in with the class schedule.

The termination of the war takes away the necessity for further interfering with medical schools, and it is highly important that these institutions be restored to their prewar status at the earliest possible moment. The orders issued thus far by the War Department indicate a rapid demobilization, and it is probable that in both premedical and medical courses the Students' Army Training Corps will soon be discontinued. The medical colleges, therefore, should arrange to extend their sessions for a month or six weeks into next summer so as to make up most if not all of the time that has been lost. If this is not done, the students' ability to secure licenses after they have completed the medical course will be jeopardized. State boards generally have expressed their willingness to make liberal allowances to meet such educational measures as might be necessary in the national emergency. Now that the emergency has disappeared, however, and there is still opportunity to make up the time lost, state boards should not be expected to relax the educational standards provided for in the practice acts. Efficient teaching in the medical schools should be at once restored.

Current Comment

FIRST AID TO OUR NAVAL FORCES

The Journal has received two copies of *The "T. B." (True Blue) Bulletin*, the "Official Publication of the United States Naval Hospital, Fort Lyon, Colo., Issued Every Saturday under the Direction of George H. Barber, Medical Director, U. S. N." It is a bright and cheery little eight-page paper, devoted to the local happenings at the Naval Hospital. Particularly interesting are some of the advertisements found in this paper. The first to attract attention is a picture of a blooming damsel with hair hanging down below her waist; our sailors are told: "Girls, try this. It doubles the beauty of your hair in a few moments." "This" was "Danderine." On the next page is a picture of an anxious mother looking at her little girl's tongue: "Look at the tongue, mother! If coated, it is a sure sign that your little one's stomach, liver and bowels need a gentle, thorough cleansing at once"—and "California Syrup of Figs" will do the trick. Those of our naval forces that feel the need of something in that line may infer that they can "Get New Kidneys" by taking "Gold Medal Haarlem Oil." A kindly faced woman, holding aloft a bottle of Lydia Pinkham's Vegetable Compound, tells the boys in blue that this wonderful preparation "restored my health after everything else had failed, when passing through change of life. There is nothing like it to overcome the trying symptoms." To the sailor who has worms, "Spohn's Compound" is recommended. Those who are suffering from "Acid-Stomach," or from "Indigestion, Gas, Up-set Stomach" can take their choice of "Eatonic" and "Pape's Diapepsin." Furthermore, the sailors are told that "Every woman wants Paxtine Antiseptic Powder for Personal Hygiene." It is "Recommended by Lydia E. Pinkham's Medicine Co." The interesting information is vouchsafed that "Women Sufferers May Need Swamp Root," and "If a woman is nervous or has dizzy spells, suffers from awful pains at regular or irregular intervals, she should turn to"—"Dr. Pierce's Favorite Prescription." Those in the Naval Hospital who fear the present epidemic are assured that "Spanish Influenza can be prevented easier than it can be cured. At the first sign of a shiver or sneeze take Hill's Cascara Bromid Quinin." Those who may be suffering from "Granulated Eyelids," Eczema, or "Baby Colds" should use "Murine," "Hunt's Salve," or "Piso's," as the case may be. A large advertisement, addressed presumably to the hospital authorities, gives instructions "How to Use Vick's Vaporub in Treating Spanish Influenza." Colorado, we believe, is dry, and in any case men in the service are subject to certain restrictions, but "For coughs, colds, effects of the grip and influenza"—"Try Peruna first." Altogether, one feels that in the United States Naval Hospital at Fort Lyon, there is no excuse for sickness.

POSSIBLE DANGERS IN EUCALYPTUS OIL AND RELATED PRODUCTS

The idiosyncrasy of an occasional person to therapeutic doses of familiar drugs is an admitted possibility but not always a recognized occurrence. Various types of hypersensitiveness are encountered sufficiently often to be impressed on the minds of the clinician as experiences that need to be reckoned with. Iodid rash may be cited in illustration. The less well appreciated instances, however, deserve special notice, particularly when they are attributable to commonly used remedial agents. Barker and Rowntree[1] have called attention to evidences of intoxication obtained with myrtol, a little known drug administered in the treatment of catarrhal conditions of the respiratory mucous membrane. This terpene-containing substance is obtained by distillation of the leaves of *Myrtus communis,* as eucalyptol, the chief constituent of eucalyptus oil, is prepared from another genus *Eucalyptus* of the same natural order of plants. A review of recorded cases of intoxication, unexpected and unaccountable or otherwise, with derivatives of these myrtaceous plants reveals the occurrence of two somewhat distinct syndromes. In the one, designated myrtogenic neuropathy by Barker and Rowntree, the nervous system primarily is affected; in the other form of intoxication, the myrtogenic dermatopathy, the skin chiefly is affected, with lesions that may be erythematous or urticarial in character. The fact that eucalyptus oil has come into more extended use again in connection with chloramin therapy, and that oils from some of the myrtaceous species appear to be used in proprietary products, such as cough drops, makes a reference to the possible dangers from them timely.

A SHORT SIGHTED DRUGGIST

Those druggists who believe that pharmacy is a profession rather than a trade have for some time urged physicians to prescribe official products rather than proprietary preparations, at least, in all cases where proprietary and official products are essentially similar. A recent experience reported to The Journal from New Haven, Conn., is worth recording. Our correspondent, who, while not a physician, is especially interested in The Journal's propaganda, writes:

> I went to a nearby drug store and asked for twenty-five cents' worth of Liquor Antisepticus Alkalinus; I got one ounce! The druggist charged me fifteen cents an ounce, and ten cents for the container. Next time I fear I shall be forced to get Glycothymoline!

To penalize a man who calls for an official product, so as to drive him to ask for a "patent medicine" of the same general character, is both poor pharmacy and bad business.

Medical Mobilization and the War

Commissioning of Physicians and All Promotions Stopped

The Surgeon-General's Office advises that since 10 o'clock of the morning of November 11, the War Department discontinued the commissioning of officers in the various corps of the Army, including physicians in the Medical Corps. This condition, it is stated, is in all probability permanent and favorable consideration will not be given to applications for commissions in the Medical Corps until further notice. At the same time favorable consideration on the recommendations for the promotion of officers was discontinued and no further promotions will be made until this embargo is modified.

Demobilization of the Army

In a press interview given by the Secretary of War, Nov. 15, 1918, it was stated that the first units to be demobilized will be the Development Battalions at the camps. These battalions are made up of men who are under physical requirements, or undergoing special drill or discipline to bring them into military value.

Every man who is discharged from the Army must have a complete physical examination for permanent record. This is the great task which now devolves on the Medical Department.

In an interview by Gen. Peyton March, November 16, it was stated that some 200,000 men will be mustered out within two weeks and then when the machine is in operation, some 30,000 men will be released daily. General March stated that under the present laws, every man who is discharged is entitled to wear his uniform for a period of three months.

Officers will be listed into various groups: those who wish to apply for commissions in the Regular Army; those who wish to put themselves into a class where they can be used for future military operations will be offered commissions in the Reserve Corps; all others will be given honorable discharges. General March stated that he had issued an order to all the staff corps stating that the discharge of officers and men must keep pace with cutting down of the work, and each department has been directed to submit a list of officers and men from time to time as they can be spared for discharge.

Medical Veterans of the World's War

There has been incorporated in the District of Columbia an organization to be known as the Medical Veterans of the World's War, and on Nov. 15, 1918, the following was recorded:

CERTIFICATE OF INCORPORATION

KNOW ALL MEN BY THESE PRESENTS, THAT WE, the undersigned, all of whom are citizens of the United States, and a majority of whom are residents of the District of Columbia, desiring to associate ourselves together to form an association under the provisions of the Code of Law for the District of Columbia, enacted by Congress and approved by the President of the United States, hereby certify that,

First: The name of the association shall be Medical Veterans of the World War.

Second: The term for which it is organized shall be perpetual.

Third: The particular business, objects and purpose of the association are: To perpetuate fellowship, prepare history, secure cooperation for the mutual benefit of the medical men who served in the War of Nations, 1914-1918, and for the mutual improvement and social intercouse of its members.

Fourth: The number of trustees who shall manage the affairs of the association for the first year of its existence, and until otherwise provided, shall be seven, who shall be the incorporators named below; and nothing herein contained shall prevent the association in increasing the number of trustees for any subsequent year of its existence.

IN WITNESS WHEREOF we, Frederick F. Russell, Edward R. Stitt, James C. Perry, James S. Easby-Smith, Victor C. Vaughan, William J. Mayo and Hubert Work, have hereunto subscribed our names and affixed our seals this fifteenth of November, A. D., 1918.

FREDERICK F. RUSSELL
EDWARD R. STITT
JAMES C. PERRY
JAMES S. EASBY-SMITH
VICTOR C. VAUGHAN
WILLIAM J. MAYO
HUBERT WORK

District of Columbia, ss:

I, N. Curtis Lammond, a Notary Public in and for the district aforesaid, do hereby certify that Frederick F. Russell, Edward R. Stitt, James C. Perry, James S. Easby-Smith, Victor C. Vaughan, William J. Mayo and Hubert Work, parties to a certain certificate of incorporation bearing date on the 15th day of November A. D., 1918, and hereto annexed, personally appeared before me, in the district aforesaid, the said Frederick F. Russell, Edward R. Stitt, James C. Perry, James S. Easby-Smith, Victor C. Vaughan, William J. Mayo and Hubert Work, being personally well known to me to be the persons who executed the said certificate, and acknowledged the same to be their act and deed for the purposes therein named.

Given under my hand and notary seal this 15th day of November, A. D., 1918.

N. CURTIS LAMMOND, Notary Public.

The several federal departments and civilian organizations cooperating in the formation of this new association are as follows:

INCORPORATORS	REPRESENTING
Colonel Frederick F. Russell	The Surgeon-General of the Army
Rear Admiral Edward R. Stitt	The Surgeon-General of the Navy
Asst. Surg.-Gen. James C. Perry	The Surg.-Gen. of Pub. H. Service
Colonel James S. Easby-Smith	The Provost Marshal General
Colonel Victor C. Vaughan	The Assn. of Mil. Surgeons
Colonel William J. Mayo	The Am. College of Surgeons
Lieut.-Col. Hubert Work	The American Medical Association

It is proposed that the membership of the Medical Veterans of the World's War shall include (a) all medical *officers who have served in the Medical Corps of the U. S.* Army, the U. S. Navy, and the U. S. Public Health Service; (b) all physicians who have been officially appointed by the President, Provost Marshal-General, or the governors of states, and who have served as members of or medical examiners on Local, Medical Advisory and District Boards.

A temporary organization has been effected, and a committee appointed to draft a constitution and by-laws.

HUBERT WORK, President.
FREDERICK F. RUSSELL, Secretary.
Officers of the temporary organization.

Red Cross Mission to Siberia

We are informed by Dr. Rudis-Jicinsky that the American National Red Cross is sending a mission to Russia, Serbia and other Slavic lands. This mission, consisting of the following personnel, will sail about the first of December for Siberia:

Surgeons: Dr. J. Cepelka, 1900 Blue Island Ave., Chicago; Dr. Henry Otradovec, 455 W. 63d St., Chicago; Dr. Fred A. Sedlacek, 1270 S. 13th St., Omaha; Dr. Emil E. Tanner, 628 Chestnut St., Milwaukee.

Internists: Dr. Charles Neumann, 1328 W. 18th St., Chicago; Dr. V. Anyz, Blue Island Ave., Chicago.

Tuberculosis Specialists: Dr. A. J. Moravek, Rio, N. Y.; Dr. Karel B. Blahnik, 1901 W. 47th St., Chicago.

Roentgenologist: Dr. J. Rudis-Jicinsky, 1900 Blue Island Ave., Chicago.

Oculist: Dr. Georgia Dvorak Theobald, South Ashland Ave. and 18th St., Chicago.

Dentists: Dr. B. K. Simonek, 1669 Blue Island Ave., Chicago; Dr. Rudolph Klicka, 616 Chestnut St., Pittsburgh; Dr. Charles Stepanek, 3634 W. 26th St., Chicago; Dr. F. R. Vasko, 1270 S. 13th St., Omaha; Dr. J. A. Shambora, 907 G St., Washington, D. C.; Dr. A. Zadrazil, Second Ave. E., 107, Cedar Rapids, Iowa; Dr. Frank V. Nemecek, 342 E. 72d St., New York.

Laboratory technician and metabolist: J. Novak, 1867 Blue Island Ave., Chicago.

Pharmacist: O. J. Pelikan, 2601 S. Lawndale Ave., Chicago.

Influenza at the Camp Brooks Open Air Hospital

The State of Massachusetts has prepared for distribution in pamphlet form the report of Major Thomas F. Harrington, medical officer in charge, on the open air camp at Corey Hill, Brookline, for the treatment of influenza among the boys in training on the receiving ships *Meade, Cobb, Dingley* and *Austin* of the merchant marine service of the state. The work at this camp has attracted attention on account of the adoption of the open air and sunshine method of caring for the patients and the employment of wire masks covered with gauze for every one coming in contact with the patients, for both of which features priority is claimed for this camp. A low incidence of pneumonia and other complications and a low death rate were among the results of this method of handling patients adopted in the hospital, as shown by the report.

The establishment of the hospital equipped to receive patients September 9, within seven hours after the work was started, and the actual receipt of thirty-eight patients at the end of that period is pointed to as an example of rapid and efficient work by the military authorities of the state and of the foresight of Governor McCall in providing equipment and supplies for such an emergency. The hospital, which was built of tents, except for portable buildings set up later for the staff and the nurses, was erected by companies of the state guard.

The medical staff consisted of the chief medical officer, commanding officer of the camp, eight physicians on night service and ten on day service, with two bacteriologists, chief nurse, head nurse for each ward, with one trained nurse, two nurse's aides and two orderlies for each. The wards consisted of thirteen tents, twelve to be occupied by one or two patients each, the thirteenth for the head ward nurse and for certain equipment to aid in carrying out prophylactic measures. All tents and the whole camp was properly drained, proper latrines and sewerage provided, water in sufficient supply, cooking facilities and an abundance of food and many luxuries arranged for from the start.

During the existence of the hospital, September 9 to October 12, there were 351 patients treated, representing the seriously ill among 1,200 men affected with influenza out of a group of more than 5,100 sailors, the deaths amounting to but thirty-six among the 351 patients.

The preventive measures may be summarized as follows: All persons coming in contact with patients to wear five layers of gauze on a wire mask over nose and mouth while near patients, gauze not to come in contact with nostrils or mouth and to be changed every two hours; hands of physicians, nurses and orderlies to be washed in bichlorid solution 1:1,000 after each contact with patients; separation of dishes and utensils used by patients and thorough boiling of same after each use; paper plates, drinking cups and napkins for pneumonia and meningitis patients; gloves and gowns, including head covering, for every one coming in contact with patients; prohibition of use of all common drinking cups, towels, etc.; thorough washing of hands of nurse before eating; gargle and mouth wash of Dobell's solution, etc.; application of argyrol ointment (10 per cent.) to nasal mucous membrane twice daily as a preventive against ear infection; use of paper bags with gauze, in place of sputum cups, to be pinned to pillow cases.

General measures were, outdoor treatment, with a maximum of sunshine and of fresh air day and night, with provision for warming the patient during the night by hot bricks, hot water bottles, extra blankets or paper sheets; four-hour feeding throughout the entire course of the fever; free catharsis by calomel, compound cathartic pill, sodium phosphate, magnesium sulphate, etc.

In the way of special medication were sponging for fever, coal tar preparations, acetylsalicylic acid, quinin, salicylates; for cough, brown mixture, Dover's powder, codein and expectorant mixture; for throat, mentholated throat tablets, Dobell's spray, red gum lozenges; for kidney irritation, hexamethylenamin, spirit of nitrous ether, milk; for nosebleed, plugging with cotton saturated with epinephrin solution; for heart, digipuratum, digifolin, camphor in oil, strychnin: for pneumonia, cotton or paper jackets, forced feeding, calcium iodid, codein, morphin, atropin, bromids, expectorant mixture and oxygen inhalation; for delirium, bromids, codein, ipecac; for meningitis, Flexner's serum; for arthritis, sodium salicylate; for convalescence, tonics of iron, arsenic and strychnin.

The preventive and medication measures as employed in the camp emphasize that the rigid enforcement of prevention guarantees protection to those brought in intimate contact with infected persons, and that drug treatment is secondary in value to forced feeding, warmth and an abundance of fresh air and sunshine.

On the subject of mask protection it is said that among a personnel of 15 physicians, 45 nurses and aids, 20 sanitary corps men and 74 sailors acting as orderlies, many of whom, especially among the latter, were changed frequently, only six nurses and two orderlies developed influenza, and it was possible to trace exposure outside the camp in five of these cases.

The term influenza-pneumonia is suggested for the type of pneumonia associated with the epidemic. It is distinctly a septicemia, and few cases occurred in which there was a positive, frank pneumonia of a specific type. There were 122 cases diagnosed either clinically or bacteriologically as pneumonia, divided roughly into 56 lobar and 66 bronchial. The mortality was 29 out of 36 deaths; a percentage of 10.16 pneumonics among 1,200 cases of influenza, and a mortality of 8.26 per cent. from pneumonia among the 351 patients treated. The percentage of pneumonia among the patients received at the hospital was 34.7.

COMMISSIONS OFFERED AND ORDERS TO DUTY ON ACCEPTANCE

[Note.—As stated elsewhere the issuing of all commissions was stopped, November 11, at 10 a. m. Therefore many of the commissions here indicated as offered may not have been received.—Ed.]

Alabama

To Camp Beauregard, La., Lieut. E. H. COUCH, Union Grove.

To Camp McClellan, Ala., Lieut. R. C. PARTLOW, Tuscaloosa.

To Camp Meade, Md., for special instruction, Lieut. G. L. WOOD, Haleburg.

To Fort Oglethorpe for instruction, Lieuts. L. A. KILPATRICK, Altoona; C. W. JONES, Boothton; G. C. REYNOLDS, Brundidge; C. N. LACEY, Demopolis; H. S. MUSTARD, Florence; R. L. HILL, Lynn; E. W. GRAY, Sheffield.

To report to the commanding general, Southeastern Department, Lieut. M. T. C. SCOTT, Headland.

Alaska

To Camp Dix, N. J., base hospital, for instruction, Capt. C. W. WELCH, Candle.

To Fort Riley for instruction, Lieut. A. LOVAS, Anchorage.

Arizona

To Camp Cody, N. M., Lieut. S. B. NORRIS, Tucson. *To examine the command* for nervous and mental diseases, Capt. P. B. NEWCOMB, Phoenix.

To Fort Riley for instruction, Lieuts. K. M. GILBERT, Chandler; H. C. MOORE, Silverbell.

To report to the commanding general, Central Department, Capt. L. E. SCHOCH, Phoenix.

Arkansas

To Camp Joseph E. Johnston, Fla., Lieut. W. P. MOORE, Little Rock.

To Camp Pike, Ark., Lieut. E. A. PURDUM, Hot Springs.

To Fort Oglethorpe for instruction, Capt. W. L. KITCHENS, Stamps, Lieut. W. E. JONES, Paris.

To Fort Riley, Lieut. J. E. JOHNSON, Fort Smith. For instruction, Lieuts. M. S. CRAIG, Batesville; R. N. MANLEY, Clarksville; E. D. ERWIN, Monticello; H. A. MURPHY, Wesson.

California

To Arcadia, Calif., Lieut. E. G. MATTISON, Pasadena.

To Camp Dodge, Iowa, base hospital, for instruction, Major C. E. PHILLIPS, Los Angeles.

To Camp Fremont, Calif., Capt. A. C. MATHEWS, Napa. Base hospital, Capt. G. W. BROWN, Los Angeles. Base hospital, for instruction, Capt. F. CUTTLE, Hanford; Lieut. J. J. O'BRIEN, Los Angeles.

To Camp Kearney, Calif., Capts. R. W. BUCKNAM, E. E. SHERRARD, Los Angeles; J. D. BALL, Oakland; M. W. HAWORTH, Sacramento; Lieuts. E. M. GRIMMER, Irvington; C. W. SHIREY, Lankershim; S. J. BECKA, J. F. HOLLERAN, O. I. TOWER, Los Angeles; R. E. MAXWELL, Randsburg; J. W. BROWNLIE, Vallejo. Base hospital, Lieut. E. E. PATERSON, Oakland. Base hospital, for instruction, Capt. C. T. Resignation of Assistant Surgeon LYNNE A. FULLERTON accepted by the President, to be effective Oct. 31, 1918.

Occupational Disease as Distinguished from Industrial Accident.—The Ohio Supreme Court in a recent decision made the following distinction between an occupational disease and an industrial accident, which, as the *Ohio State Medical Journal* for April says, will be of interest to those engaged in the industrial side of public health work. The court says: "A disease contracted in the natural and ordinary course of employment, by a person engaged in a particular calling or occupation, which disease from common experience is known to be a usual and customary incident to such calling or occupation, is an 'occupational disease,' and not within the contemplation of the workmen's compensation law." It is also said with reference to a particular case: "The accidental and unforeseen inhaling by an employee, in the course of his employment, of a specific volatile poison or gas, resulting in injury or death, is not an occupational disease."

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Upholds Ordinance Regarding Closing.—The supreme court of the state has upheld the validity of an ordinance of the city of Los Angeles prohibiting public gatherings during the epidemic of influenza. The court denied a writ of habeas corpus in the case of five citizens of Los Angeles who, in defiance of the prohibiting ordinance, were arrested for holding a service in the Christian science church. The constitutionality of the health ordinance was attacked.

ILLINOIS

Restrained from Halting Hospital Work.—In the superior court, November 9, Judge Foell issued a temporary injunction restraining the village of Broadview from interfering with the construction of a hospital which is being erected at Speedway Park.

Illegal Practitioners Arrested.—Milton Chaiken of Joliet, who was recently arrested by the Department of Registration and Education of the State of Illinois and fined $75 and costs for violating the Medical Practice Act, was again arraigned in court and fined $50 and costs on each of six counts. Chaiken was employed in the office of a so-called advertising physician in Joliet. When the physician was out of the office Chaiken would diagnose cases and write prescriptions, signing the name of the physician to them.——Julia Badurak, also of Joliet, was arrested by the department and fined $100 and costs for practicing medicine without a license.

Campaign in Illinois for Tuberculosis Sanatoriums Successful.—In the election held November 5, thirty-three of the 102 counties in Illinois voted affirmatively on the levy of a county tax of 3 mills or less for the construction of tuberculosis hospitals and the establishment of nursing, clinic and dispensary service in each county. The campaign plan prepared by the Illinois Tuberculosis Association provided for widespread publicity and personal contact by local workers with the families of the various counties. The general direction of the campaign was in the hands of Walter B. Thurber, executive secretary of the Illinois Tuberculosis Association, and a staff of three field workers and the chairman of each county committee made up the board directing the campaign. This election gives Illinois a total of forty such institutions as compared to none two years ago.

Chicago

Influenza and Pneumonia Deaths.—The combined reports of influenza and pneumonia in Chicago for the months of September and October, covering the wave of influenza, show that there were 7,930 deaths.

Personal.—Dr. Truman W. Brophy has returned after three months spent in the treatment of facial and head wounds in France.——Dr. Gerhardt E. Wyneken resigned from the faculty of Loyola University, October 4.——Dr. Willis O. Nance, who has been a member of the city council for eight years and for seven years has been chairman of the council committee on public health, was elected trustee of the Sanitary District of Chicago, at the recent election.——Dr. Franklin A. Weatherford, while making a professional call, October 24, suffered a cerebral hemorrhage and is seriously ill at the Englewood Hospital.

INDIANA

Provision for Returned Tuberculous Soldiers.—According to a statement by M. E. Foley, chairman of the state council of defense, only 370 beds have been provided in the entire state for returned tuberculous soldiers, and more than 90 per cent. of the counties of the state have made no provision for the care of such men.

Personal.—Dr. J. Clifford Wallace has been appointed deputy health officer of Fort Wayne.——Dr. Eric A. Crull, city health commissioner of Fort Wayne, has resigned to enter the military service.——Dr. Lindley H. Eshleman, Marion, is reported to be seriously ill with an infection of the leg.——Dr. Henry W. Greist, Monticello, has been appointed health commissioner of White County, to succeed Dr. Alfred C. Williams, Reynolds, who has resigned to enter the military service.——Dr. Charles P. Cook, New Albany, is said to be critically ill with pneumonia.

Camp Faces Crisis.—Boehne Camp, the tuberculosis sanatorium of Vanderburg County, is facing a critical financial situation. Unless $25,000 is raised for the support of the camp, the institution will be forced to close. The cost of maintaining the hospital until January 1 will be $13,000, including the payment of back debts and general running expenses. The barracks, now nearly completed, which will accommodate from fifty to sixty soldiers cannot be opened until a mess hall and kitchen have been erected to care for the needs of these men. The influenza epidemic is believed to have increased the predisposition toward tuberculosis. These three factors unite in making the situation urgent.

Reappearance of Influenza.—On November 18 the Indianapolis Board of Health issued an order providing for the universal wearing of cloth masks in all public places in the city and the closing of the public schools. This action was taken on account of the very serious recrudescence of epidemic influenza in the city, and on account of its apparent reappearance in various communities throughout the state. The situation in Indianapolis is described as being as serious as at any time during the epidemic, and in addition to the closing of the schools and the order requiring masks, which was to be in full force by November 20, the matter of again closing theaters and other places of public gathering, including the churches, was under advisement. City Health Officer Dr. H. G. Morgan attributes the new accession of the disease to carelessness of the people during the recent war celebrations. Reports received at the office of the state board of health show that the disease is also spreading throughout the state. Thirty-eight counties reported 1,439 new cases for the week end. Green County reported 135 new cases, Vigo 158, Cass 77, Decatur 60, Grant 63, Jasper 70, Laport 65, Clay 66 and Switzerland 54. Among the places reporting a more serious condition with regard to influenza are Frankfort, with 46 new cases, November 18; Columbus with 30; Rockville, where it is said there were more cases than at any time during the epidemic, and Alexandria, Brazil, Shelbyville, Seymour and Huntington.

MARYLAND

Board Meeting to Be Omitted.—Owing to general conditions and the limited number of inquiries concerning the December examination for licensure, the Board of Medical Examiners of Maryland announces that it has determined to omit the usual December meeting.

Government to Study Influenza Here.—Dr. Wade H. Frost and a staff of assistants from the United States Public Health Service visited Baltimore during the past week for the purpose of studying the recent epidemic of Spanish influenza in the city and state. They were given access to the records of the state department of health and the city health department.

Personal.—Dr. Daniel Z. Dunott, Baltimore, has been named chairman of the Committee on Health and Medical Relief of the United States Railroad Administration, which work includes all railroads in this country.——Dr. Ralph B. Seem, acting superintendent of Johns Hopkins Hospital, Baltimore, sustained a severe wrench of the shoulder, and Dr. Benjamin R. Benson, Cockeysville, suffered contusions in a collision between automobiles near Cockeysville, October 28.

MASSACHUSETTS

Hospital Items.—It is announced in the Boston papers that papers are about to be signed under which the Parker Hill Hospital property, controlled by the Women's Charity Club and the Massachusetts Women's Hospital Corporation, will be transferred to the government. This building with seventy-five beds will be used for headquarters for nurses, especially those who work in the Robert Bent Brigham and Elks hospitals.——Edward S. Searles, Methuen, has offered to build a hospital near Lawrence for the treatment of patients residing in Lawrence, Methuen and Andover.

NEW YORK

Planning Venereal Disease Hospital for Syracuse.—At the suggestion of Dr. David M. Totman, health officer of Syracuse, the mayor of that city, after a conference with a number of prominent citizens, has appointed a committee to choose a building that can be converted into an isolation hospital for cases of venereal disease.

Personal.—Dr. John W. LeSeur has been appointed acting health officer of Batavia in the place of Dr. Victor M. Rice, who has accepted a captain's commission in the United States Army.——Dr. John A. Wyeth is confined to his bed in the Polyclinic Hospital with a broken ankle, caused by slipping and falling on a polished floor.

New York City

Hospital Transferred.—The trustees of the New York Polyclinic Hospital have proposed to transfer the property of that institution to the Columbia University to be maintained for the public, and for advanced instruction and research in medicine and surgery. The hospital was built in 1912, and has a capacity for 300 patients.

Lecture on Pasteur.—Dr. Etienne Burnet of the Pasteur Institute, Paris, surgeon in the French army and member of the Mission of French Scholars to the United States, delivered a lecture at the New York Academy of Medicine in cooperation with Columbia University, November 15, on "Pasteur as a Representative of the French Scientific Spirit."

Red Cross Gifts.—The Atlantic Division of the Red Cross will receive $1,000,000 from the estate of James A. Schrymser. This is said to be the largest single bequest the organization has ever received.——The employees of the supply department of the Brooklyn Navy Yard have raised money for a fully equipped ambulance for overseas service, which they have turned over to the American Red Cross.

The Influenza Toll in New York.—An announcement from the health department, November 16, states that although new cases of influenza continue to be reported the epidemic is practically over in this city. From the beginning of the outbreak until November 16, 128,558 cases have been reported and 19,091 cases of pneumonia, with 20,086 deaths from the two causes. It is estimated that in the Bronx there were 40,000 cases, while only 18,000 were reported.

Dinner to Bastianelli.—The Italian Medical Society of New York City recently gave a dinner to Lieut.-Col. Bastianelli of the Italian army. Dr. Carmelo Atonna, president of the society, in his introductory remarks, suggested that Colonel Bastianelli should do all in his power in Rome to bring about an interchange of medical professors between the United States and Italy, and in his reply Dr. Bastianelli agreed to this and urged the Italian medical fraternity of New York to unite in an effort to form a real Italian medical center.

Plan Great Chemical Institute.—At a recent meeting of the New York branch of the American Chemical Society held at the Chemists' Club, resolutions were passed proposing the organization of an American Chemical Institute under the auspices of the American Chemical Society, whose special function shall be to promote research with a view to the introduction of new or improved medicinal products, so as to make the United States free of any future effort to control this field by German manufacturers. In the discussion of the resolution Dr. Phoebus A. Levene of the Rockefeller Institute gave the project his earnest support.

Harvey Society Meeting.—At the annual meeting of the Harvey Society held in September, the following officers were elected: president, Dr. Graham Lusk; vice president, Dr. Rufus J. Cole; secretary, Dr. Karl M. Vogel, and treasurer, Dr. F. H. Pike. It was decided that the lectures to be given this winter should not exceed six, and that the lectures of last winter and this winter be given in one course, the members to be charged with dues for one year only to cover the dues of activity. The two lectures which had been arranged to be held, one by Dr. Stewart Paton, Princeton, N. J., on "The Psychology of the Aviator," and the other by Dr. Alonzo E. Taylor, Philadelphia, on "The World's Food Situation," have been postponed on account of the departure of the lecturers for Europe. The following lectures have, however, been provisionally arranged:

Jan. 11—Col. Eugene R. Whitemore, Infectious Diseases in the Army.
Jan. 25—Dr. R. N. Yerkes, Psychological Examination of the Soldier.
Feb. 8—Dr. Yandell Henderson, Physiology of the Aviator.
March 1—Dr. Frederic S. Lee, Industrial Fatigue.
March 15—Col. F. P. Underhill, War Gases.

OHIO

Personal.—Dr. Fletcher Langdon, Cincinnati, has been appointed bacteriologist of the Cincinnati Board of Health, to succeed Dr. Philip H. Dorger, who has been ordered to report to Yale University for training in the Medical Reserve Corps.

Follow-Up Work on Tuberculosis.—Up to November 1, discharges of soldiers for tuberculosis reported to the state authorities amounted to 865. Of these, there were only 125 recorded to the state department of health as not found. The others have been referred to local public health nurses, reached by letters or visited by nurses from the state department of health. Of the Ohio soldiers discharged on account of tuberculosis, thirty-one have been placed in hospitals.

Reorganization of Local Health Machinery.—The state board of health is formulating plans for the reorganization of the local health administrative system. The chief defects are the lack of trained men in the local health administrative work and the absence of control over local health officials by the state department of health. The proposed plans call for the grouping of the 2,200 health districts of the state into larger units, able to support efficient local health organizations. The coming of peace will aid by releasing for public health work many men who have received training in sanitary work of the Army.

Recrudescence of Influenza.—A bulletin of the state department of health, November 16, says that in some communities of the state, following the permission of the state board to local health officers to determine when the influenza ban should be lifted, premature action resulted in a recrudescence of the disease. In some districts the ban was lifted in cities and towns when the disease was still prevalent in rural surrounding territory, with the result that the country people came to town to attend movies and other public places, again scattering the infection. The general situation with regard to influenza, however, was much improved, and United States Public Health Service physicians sent into the state to help out are being rapidly released.

PENNSYLVANIA

Personal.—Dr. Glenn M. Pierce, McKeesport, who has been confined to his bed for four weeks with influenza and pneumonia, is reported to be convalescent.

Quarantine Lifted.—The quarantine for epidemic influenza was almost entirely lifted from the state, November 9, the only exceptions being a few counties in which conditions have not improved. Among the exceptions are Blossburg, Scottdale, Jeannette, Monessen and Vandegrift, Carnegie, Oakdale, Calamity, Unity Mills, Forest County, Newport, Perry County, Muncy, Renovo, Bitumen, Snowshoe, Sandy Ridge, Hyndman, Broad Top, Liberty, Osceola Mills, Three Springs, Robertsdale, Forest City, Dunmore and Arnot counties.

Bucks County Medical Society.—The Bucks County Medical Society held its annual session, November 13, at Monument House, Doylestown. Dr. B. Franklin Royer, acting commissioner of health, was a guest of honor. The following officers were elected: president, Dr. Isaac S. Plymire, Doylestown; vice presidents, Dr. William F. Weisel, Quakertown, and Dr. James Collins, Bristol; secretary-treasurer, Dr. Anthony F. Meyers, Blooming Glen; censors, Dr. George M. Grim, Ottsville; Dr. William R. Cooper, Point Pleasant, and Dr. Howard Pursell, Bristol.

Philadelphia

Influenza Declining.—During the week ending November 8, there were 375 deaths from influenza and pneumonia, 218 from the former and 157 from the latter. The total fatalities for the week were 802, as compared with 1,771 the previous week and more than 5,000 at the height of the epidemic.

Hospital Bequests.—The Episcopal Hospital eventually will receive $5,000 from the estate of Mrs. E. C. Swartz, to endow two beds, one for men and the other for women "engaged in or connected with the publishing, printing or writing for newspapers in Philadelphia, as a memorial to my late husband, Edward J. Swartz," former editor-in-chief of the *Evening Telegraph*.

Hospital Taken by United States.—Hahnemann Hospital, having been taken over by the government, has been made central receiving and examining station for medical student applicants who desire to go to the officers' training camps. Col. John A. Lockwood is in charge of the work at the hospital, which is to be devoted entirely to obtaining officers for the Medical Corps, although those selecting infantry, machine gun or artillery will be examined and, if qualified, sent to camps devoted to those branches.

Epidemic Orphans to Be Cared For.—A preliminary conference of representatives of various aid organizations met in the office of Director Krusen to plan for the care of children made orphans by the death of their parents during the recent epidemic of influenza. The organizationss represented were the Emergency Aid Committee, the National Congress of Mothers, the Division of Child Hygiene, Department of Public Works, the Social Service Department, Philadelphia General Hospital and the Children's Aid Society. It was decided to make an appeal to the public for subscriptions for a fund of $50,000 for their care and maintenance.

Campaign for Pennsylvania Hospital.—The Pennsylvania Hospital's drive to raise $1,000,000 to enlarge its equipment began the first week in November. Nearly 30,000 letters have been sent out, stating the needs of the hospital and telling of its accomplishments since its establishment, 167 years ago. According to the report of the board of managers, there was a deficit of $116,000 last year and this year it threatens to be greater. In the last year more than 50,000 patients were treated at the Pine Street department, the majority of whom paid nothing. Since the branch for nervous and mental diseases was opened in West Philadelphia, more than 19,000 cases have been treated, 7,000 being restored to normal. The expense of the charity department last year reached $174,000 and of the mental department, $142,000.

Personal.—Dr. J. H. Mason Knox, Baltimore, assistant director, children's bureau. American Red Cross in France, addressed the Philadelphia County Medical Society and Babies' Welfare Association, November 13, on "What the American Red Cross is Doing for French Children, and Its Application at Home."——Major Raymond G. Hussey deliverd the Gross Lecture before the Pathological Society of Philadelphia, November 14, his subject being "Army Medical Laboratory Work in France."——Dr. Mary E. M. Loog has been appointed assistant school medical inspector.——Dr. Alonzo E. Taylor, former professor at the University of Pennsylvania, sailed for Europe, November 16, to be Mr. Herbert Hoover's assistant in the task of rationing Germany. Dr. Taylor will represent both the food administration and the war trade and it is expected that he will go to the Balkans and take charge of the situation there.——Major John W. H. Pollard, U. S. M. C., has been appointed attending surgeon of the Army for the city of Philadelphia.

TENNESSEE

Personal.—Dr. Matthew C. McGannon, Nashville, has been appointed chairman of the British Recruiting Mission for the Nashville District.——Dr. Ben H. Brown, former food inspector of Chattanooga, has been appointed director of health of the city.——Dr. Owen K. Womack has been appointed local surgeon for the Louisville and Nashville system at McKinnon.——Dr. Eugene L. Bishop, Columbia, has been appointed state director of rural sanitation and state epidemiologist.

Hospital News.—Accommodation for ninety-two nurses has been provided at the Knoxville General Hospital, in a nurses' home which is now almost completed. This home takes in the buildings formerly used by the Tennessee Medical College and the laboratory.——Two tent-houses are to be erected at the United States Marine Hospital, Memphis. They will have wooden floors and will be weatherboarded for about 4 feet from the floor, and will be used as quarters for sufferers from tuberculosis.——A health resort is to be erected in the Lookout Mountain Hospital on the top of Lookout Mountain by Dr. Clair C. Patch, Graysville.——The board of directors of the East Tennessee Sanatorium for Tuberculosis has submitted to the government plans for a building and has requested permission to build. The plans provide to accommodate fifty patients, and the cost will be about $40,000.

TEXAS

New Hospital.—Formal approval of plans for a modern military hospital on the grounds of the State Agriculture College, College Station, is reported by the president. The hospital will be a frame construction, and will cost about $56,000.

Personal.—Dr. William W. Samuell, Dallas, who has been seriously ill with influenza, is reported to be convalescent. ——Dr. H. Reid Robinson, Galveston, who has been seriously ill at St. Paul's Sanitarium, Dallas, is reported to be improving slowly.——Dr. Oscar H. Mengel, Frackville, is ill at his home with pneumonia following influenza.

WISCONSIN

Fees Held by County.—Hundreds of dollars, fees for making out birth certificates, are awaiting Milwaukee physicians and midwives in the office of the county clerk.

Emergency Hospital Opened.—An emergency hospital has been opened by the local Red Cross chapter in the Garfield School building, Washburn, for the care of cases of influenza.

Personal.—Dr. Arthur G. Benson, Viroqua, who has been seriously ill with pneumonia following influenza, is now believed to be out of danger.——Dr. Wilbur G. Melaas, Beloit, is reported to be seriously ill with rheumatic arthritis.

Sanatorium News.—Work will begin within a few days on the excavation for the tricounty tuberculosis sanatorium to be built by Bayfield, Madison and Iron counties, at Salmo, about 5 miles north of Washburn. The name adopted for the sanatorium is the Pureair Sanatorium and the buildings will be erected at a cost of about $68,000.——A sanatorium has been offered to the Madison Anti-Tuberculosis Association by Dr. Charles H. Vilas. The sanatorium consists of five buildings on a site in Blooming Grove. It is equipped with heating furnaces and grates, an electric light and power system, artesian water, intercommunicating telephones and furnishings. This is offered to the association by Dr. Vilas in memory of his mother, Esther Smilie Vilas. The gift of Dr. Vilas was accepted by W. S. Heddles, at the meeting of the association, October 8. Dr. Louis R. Head, Madison, president of the association, is to be director of the hospital.

WYOMING

Personal.—Dr. Horace P. Holmes, for many years a practitioner of Sheridan, is reported to have been adjudged insane, October 15, and to have been committed to the State Hospital, Evanston.——Dr. J. Hoyt Huckins has been appointed superintendent of the Wyoming School for Defectives, Lander, to succeed Dr. Thomas G. Maghee.——Dr. John H. Young, San Diego, surgeon of the Union Pacific Gold Company at Rock Springs for the last eighteen years, was presented with a gold watch and fob by the officials and employees of the company, recently, in recognition of his services as company physician.

CANADA

Personal.—Col. George E. Armstrong, C. M. G., Montreal, will read a paper before the Academy of Medicine, Toronto, December 3, on "The Effect of the War on Surgery, Civil and Military."——Capt. Charles F. Atkinson, C. A. M. C., Edmonton, Alta., has been awarded the military cross.——Col. Gilbert Royce, M. D., has returned to Toronto from overseas.

Total of Canadian Casualties.—Ottawa issued, November 15, statistics as to the Canadian casualties up to that date. More than 55,000 Canadian soldiers have given up their lives in the war, all the casualties totalling 213,268, but these will be increased after the returns for Mons are in. To date the casualties are: killed in action, 35,128; died of wounds, 12,048; died of disease, 3,409; presumed dead, 4,620; missing, 842; wounded, 154,361; prisoners of war, 2,860.

Influenza Statistics for Toronto.—Dr. Charles J. C. O. Hastings, Toronto, medical officer of health, has compiled the following figures relative to the deaths from influenza and pneumonia: under 1 year of age, 44; from 2 to 9, 146; under 10 years of age, 190; from 10 to 19, inclusive, 126; from 20 to 29, 455; from 30 to 39, 376; from 40 to 49, 94; from 50 to 59, 63; from 60 to 69, 31; from 70 to 79, 24; 80 years and over, 4, and ages not known, 15. With a population of 490,000, there were 1,614 deaths.

GENERAL

Æsculapians Meet.—The second annual meeting of the Æsculapian Society of the Wabash Valley was held at Terre Haute, Ind., this month. Dr. Joseph Hall, Westfield, Ill., was elected president.

Cancellation of Appeal for Collection of Scrap Platinum.—The chief of the section of medical industry and the chief of the platinum section announce to the doctors and dentists of the country their appreciation of the hearty response made to the call for scrap platinum, and request that no further scrap platinum be turned to the government through the channels indicated in their previous communication.

Bequests and Donations.—The following bequests and donations have recently been announced:

Malden, Mass., Hospital, $5,000 by the will of Mary Benson, Brooklyn.

United Charities, Chicago, $25,000; Chicago Home for Incurables, Home for the Friendless and Visiting Nurses' Association, each $10,000 by the will of George R. Thorne, Chicago.

Russell Sage Institute of Pathology, New York City, an endowment fund of $300,000, Adirondack Cottage Sanatorium, $25,000 by the will of Mrs. Russell Sage, New York City.

Twelve thousand dollars for the construction of a hospital for the white race, and a similar amount for provisions for negroes of the community by the will of R. J. Reynolds, Winston-Salem, N. C.

Report of Medical Commission to Ecuador.—During the summer a commission of which Dean Arthur I. Kendall, Prof. Charles A. Elliott and Prof. H. E. Redenbaugh of the Northwestern University Medical School, Chicago, were members, was sent by the Rockefeller Foundation to Ecuador to make a study of disease prevention on the west coast of South America, having in view a greater trade with that region after the war. The commission returned in October after having been well received and given every facility for the study of the questions involved, the chief of which is the prevention of yellow fever. The report will be issued soon.

Cooperative Tuberculosis Campaign. — As previously announced, the Red Cross will not conduct a Red Cross Seal campaign this year. To take the place of funds raised by this means in fighting tuberculosis the Red Cross will appropriate to the National Tuberculosis Association, $2,500,000. This will be distributed by the national association to the various state anti-tuberculosis associations and not to any local organizations, except in a few instances where independent seal campaigns have been conducted, as in New York City, Brooklyn and Pittsburgh. The appropriations will be made quarterly to the various state organizations, beginning about January 1. The state organizations will have full power to distribute the funds throughout the respective states. It is expected that each state will receive an amount equal to that heretofore raised by the sale of seals, but the exact amount cannot be stated at this time. The Red Cross will secure the money appropriated for the tuberculosis campaign by its campaign for members which will be conducted this fall. Complete arrangements with reference to the membership campaign will be announced soon.

FOREIGN

Italian Scholarship in Great Britain.—The *Riforma Medica* states that the Italian government has presented 300 pounds sterling to the Ramsay Fund, instituted in London to encourage the study of the chemical sciences. A scholarship will be assigned in Great Britain to some Italian chemist.

New Degree at Birmingham University.—As announced, May 23, 1918, by Sir Oliver Lodge, principal of Birmingham University, a degree corresponding to the Ph.D. degree will be granted at Birmingham to foreign students who enter the university for higher study. This is one of the outcomes of the war, and is intended to provide for graduate students who will not now want to go to Germany as many students formerly did.

Medical Students of Switzerland.—In the five universities of Switzerland, 1,725 students were enrolled during the summer semester. These were distributed as follows: at Basle, 220, including 174 Swiss, of whom 15 were women, and 46 foreign, of whom 4 were women; Berne, 385, including 242 Swiss, of whom 27 were women and 143 foreign, of whom 16 were women; Geneva, 381, including 163 Swiss, of whom 16 were women and 218 foreign, of whom 58 were women; Lausanne, 225, including 159 Swiss, of whom 13 were women, and 66 foreign, of whom 16 were women, and Zurich, 504, including 350 Swiss, of whom 56 were women, and 154 foreign, of whom 16 were women.

Deaths in the Profession Abroad.—Marchese E. Laureati of Pisa, for two years assistant in Maragliano's medical clinic at Genoa and later assistant at the surgical clinic at Pisa after having served for two years with an Italian expeditionary force in Africa.——Dr. E. Pena, director at one time of the Assistencia Publica of Buenos Aires and long member of the city council. He had returned recently from an official trip to Europe to study sanitary methods.——Dr. H. Hoessli, director of the Balgrist Orthopedic Institute at Zurich.——Lieut.-Col. E. F. H. Dobson of the Indian Medical Service, retired, lost when the *Hirano Maru* was torpedoed off the coast of Ireland.——Dr. J. Ubeda y Correal, inspector in chief of the medical department of the Spanish army and a leading figure in the profession in Spain.

Novaro's Retirement.—Prof. G. F. Novaro retires this year from the chair of clinical surgery at the University of Genoa, having reached the age of 75. He is a senator of the realm, and was one of the pioneers in surgery in Italy. He is said to have been the first in any land to apply gastro-enterostomy in treatment of ptosis; he also did typhlostomy for colitis, and a number of operations on the esophagus, common bile duct, etc., which at that time, as the *Riforma Medica* remarks, had not received the sanction of a foreign name. As early as 1890 his publications on the surgery of the stomach were based on extensive experience. He has presented his large library to the city of Genoa, and a special hall has been set apart for it. Funds have been appropriated or are being collected to maintain this Novaro hall permanently as an up-to-date medical library in the public library building.

CORRECTION

Incorrect Report of Death of Capt. Warren Walker.—In the October 26 issue of The Journal it was noted that Capt. Warren Walker, M. C., U. S. Army, was burned to death, October 9, at Colonia, N. J. The Journal was advised that there was a Captain Walker burned to death at this time but not the Captain Walker referred to in the item, that one having been promoted to a majority and is in active service in the office of the Surgeon-General, Washington, D. C.

LONDON LETTER

London, Oct. 31, 1918.

The Influenza Epidemic

Influenza is still widely prevalent and is imposing a great strain on physicians, who are exhausted in having to visit so many patients. Some are unable to complete the round of all the patients on their lists. In the ninety-six great towns of England and Wales, with an aggregate population estimated at 16,500,000, the number of deaths attributed to influenza last week was 4,482, of which 1,256 were in London. These figures refer only to the civil population. The deaths in London attributed to influenza amounted to nearly half the deaths from all causes. At this time of year the normal number of deaths from influenza would be only 5. The figures in the preceding three weeks were 17, 80 and 371. The effect of influenza is further shown in the rise of the general death rate. In the first week of October this corresponded to an annual rate of 12.6 per thousand, in the second week to 15.1, in the third to 20.7, and in the fourth to 30.9. Numerous conferences have taken place between representatives of the Local Government Board, the Board of Trade, and naval and military authorities, and bacteriologic investigations have been continuously made since the beginning of the summer outbreak. These show that bacteriologically this outbreak does not differ from other outbreaks of influenza, fatalities being due to secondary infections, chiefly by pneumococci and streptococci. The suggestion has been made that its severity is due to lowered nutrition consequent on food restriction; but of this there is no proof. Sir A. Geddes, minister of national service, replying to a question in Parliament as to what steps he had taken to provide an adequate medical service for the civil population in view of the present serious epidemic of influenza, said that all arrangements made in connection with the employment of physicians under the ministry of national service and all withdrawals of physicians from civil life for service with the armed forces of the crown during the past year have been made with full regard to the contingency of a widespread epidemic disease affecting the population. Influenza has been more or less prevalent in epidemic form for some months, and the calls on the civil medical profession have consequently been heavy. Simultaneously, severe fighting on a great scale in all theaters of war has imposed an additional heavy strain on our medical resources. In April, Parliament conferred powers on the minister of national service that enabled him medically to examine men of military age at any time. In view of possible emergencies this power was largely used, approximately 7,000 physicians being employed and very large numbers of men being examined. Concurrently, with the increase of influenza, the number of physicians employed on medical board work has been reduced, thereby rendering an increasingly large body of physicians available for exclusively civil practice. The number of medical board sessions has been reduced from approximately 3,500 to 1,000 a week. This has not affected recruiting, as the pool formed by examining men in advance has been sufficient to maintain the flow of men to the forces. In order further to reinforce the physicians available to attend the civil population, all medical examinations in advance are to be suspended for the present.

A conference of bacteriologists to discuss preventive vaccination for influenza has been held at the War Office under the chairmanship of Col. Sir William Leishman. The majority of those present agreed that there was considerable doubt as to the primary etiologic significance of *Bacillus influenzae* of Pfeiffer, and considered that the existence of some as yet undiscovered virus must be regarded as possible. They had, however, no doubts as to the frequent presence of Pfeiffer's organism in this epidemic, or as to the great importance of the part it played in the production of the symptoms and complications of the disease. The organisms most frequently associated with *B. influenzae* and chiefly responsible for the gravity of the secondary pulmonary complications were pneumococci and streptococci. It was unanimously agreed that a vaccine might prove valuable produced from *B. influenzae*, the pneumococcus and the streptococcus. A number of strains and types of each organism recently isolated from cases of the epidemic should be used. The first dose should consist of 30 millions of *B. influenzae*, 100 millions of pneumococcus and 40 millions of streptococcus. A second dose of twice these numbers should be given after ten days. While it would be preferable to vaccinate before exposure to infection, the vaccine need not be withheld from a body of men among whom influenza had already appeared, excepting those who have fever or are obviously ill.

Prevention of Anthrax

The departmental committee appointed in 1913 to inquire into precautions for preventing danger of infection from anthrax in the manipulation of wool, goat hair and camel hair has issued its report. Among the most important recommendations is the abandonment of the attempt to control anthrax by regulations as being totally inadequate. The committee states that the simplest, cheapest and most effective method of preventing anthrax in the various branches of the wool trade is by disinfection of wool and hair abroad. It is recommended that the British government should establish the disinfection authority and should then take steps to obtain the cooperation of the governments of other countries.

The Standardization of Clinical Thermometers

Under the Defense of the Realm regulations, the Ministry of Munitions has ordered that no clinical thermometer shall be sold which has not been tested and approved by the director of the National Physical Laboratory. For one month after the date of the order, no thermometer showing at any point in its registration of temperature an error of more than 0.4 F. will be approved. On the expiration of this period, no thermometer shall show an error exceeding 0.2 F. over the range up to 106 F. Above this temperature, the error shall not exceed 0.3 F. For thermometers graduated in degrees other than Fahrenheit, corresponding tolerances will be allowed. A thermometer will not be approved if it is not self-registering with a constriction, which must be such as to retain the index column and also allow of the mercury being reset. Approved thermometers will be marked with the National Physical Laboratory trade mark and the year of test. The charge for testing a thermometer will be 6 cents, including carriage to sender.

PARIS LETTER

Paris, Oct. 24, 1918.

Treatment of War Wounds of Nerves

This subject was discussed at the recent Twenty-seventh French Congress of Surgery, especially from the standpoint of remote results of treatment. So far as indication for operation is concerned, the majority of the surgeons who spoke were in favor of such intervention, in spite of the teachings of the neuropathologists of Bordeaux, who claim that surgical intervention in wounds of nerves is not only useless but harmful because it interferes with the regeneration of the nerve. Dr. Walther of Paris stated that operation is not performed often enough in these cases, hence too many of these men are incapacitated two and three years after the injury of the nerve because they had not been subjected to operation. This is due to the fact that for a long time physicians, and also some surgeons, have been opposed to radical resection, followed by suture or grafting, of injured nerves presenting evidence of a complete lesion and which were not responding quickly to medical treatment.

REMOTE RESULTS

Dr. Delagenière of Mans presented some interesting statistics on 338 cases of wounded nerves in which surgical treatment was employed: resection and suture, 236 cases; resection and nerve grafting, 9 cases; neurolysis or nerve liberation, 113 cases. Resection and suture was followed by 88 per cent. of successes; the 9 grafting cases yielded 3 good results and 6 failures; neurolysis has given good results only in cases of simple compression of the nerve. Dr. P. Wiart of Paris has full data on the remote results in 86 cases of projectile injury of the radial nerve in which he operated. There were 25 sutures and 61 liberations. Of the suture cases, a cure was obtained in 20 per cent. with improvement in as many more; among the neurolysis cases, 33 per cent. of cures were obtained and in 25 per cent. the patients were improved. These were all old cases, many of them being cases of long standing suppuration, with fractures. Operation done in recent cases, as early as possible, will yield far better results. Dr. L. Sencert of Nancy spoke on the subject of dead heteroplastic nerve grafts, applying to the human the experimental work done on animals by Dr. Nageotte. From a still-born calf the sciatic nerve is removed, placed in alcohol, and when sterilization is sufficient the graft is placed between the ends of the divided nerve and sutured in place. This method has given good results experimentally on animals, and Sencert has used it in the human for a loss of substance of 10, 12 or 13 cm. of the nerve. Sencert recommends the use of this method, in preference to other graft methods, in all cases in which there is a considerable gap in a nerve.

Treatment of Tuberculosis with Injections of Saccharose

For some time one of the daily papers has made a strong propaganda in favor of the treatment of tuberculosis according to the method of Dr. Lo Monaco of the University of Rome. Inasmuch as the readers of The Journal have been interested in this method, it will be interesting to refer to some experiments that have been made in France.

At the last meeting of the Société de thérapeutique, Dr. Louis Rénon and Dr. Mignot reported the results of their researches on the treatment of human and experimental tuberculosis by means of injections of saccharose. Guinea-pigs were inoculated with tubercle bacilli and then injected with saccharose. The disease was not modified in any way. In fact, these guinea-pigs died sooner than others similarly inoculated but not injected with saccharose. Among the humans the results were also negative, not only in the pulmonary cases but also in the bone and peritoneal cases of tuberculosis. Therefore, the authors conclude that these injections are ineffective in both experimental and human tuberculosis. Dr. Sergent of Paris, who has also investigated Lo Monaco's method, stated that while there was a slight, but inconstant, improvement in the general condition of the patient, manifested merely as a state of *bien-être* (well-being), the evolution of the disease was not modified. Dr. Robin of Paris has arrived at the same conclusion as the previous speakers. These clinical and experimental observations show that Lo Monaco's method does not possess the marvelous efficacy with which it is endowed by the lay press.

Less Stringent Regulations on Flour Consumption

M. Victor Boret, minister of agriculture and food commissioner, has submitted to the president of the Republic a decree authorizing for use as food the flour of all cereals, such as corn, rye, méteil (a mixture of wheat and rye) and buckwheat, the use of which was prohibited during the war except for baking bread. But the use of these cereals will be permitted only for purposes already authorized and within very narrow limits. However, the decree amplifies the bread and flour tickets. Henceforth, a 100 gram ticket entitles the holder to 80 grams of regulation bread (in lieu of 50 grams) and 75 grams of flour (in lieu of 50 grams), as heretofore.

Death of Dr. Braillon

Dr. Braillon, professor of clinical medicine in the Ecole de médecine et de pharmacie at Amiens, died from an infection contracted from our wounded soldiers to whom he was ministering.

Marriages

Lieut. Lucius Lamar Terry, M. C., U. S. Army, Bessemer, Ala., on duty with the Thirty-First Division, Camp Wheeler, Ga., and now overseas, to Miss Bess Gilder of Carbon Hill, Ala., recently.

Prentiss Edward Parker, Bourg, La., to Miss Annie Mainer Williams of Livingston, Texas., at New Orleans, October 11.

Asst. Surg. Richard Parker Bell, Lieut. (j. g.) U. S. Navy, assigned to duty on *U. S. S. Charleston*, to Miss Dunham of Lakewood, Cleveland, October 26.

Lieut. Pierre Numa Charbonnet, M. C., U. S. Army, New Orleans, to Miss Blanche Joan Rogers of Winfield, Kan., at Waynesville, N. C., October 22.

John Allan Wyeth, New York City, to Miss Marguerite Chalifoux of Boston, November 15.

Deaths

Lieut.-Col. Alexander Watson Williams, M. C., U. S. Army ⊕ Johns Hopkins University, Baltimore, 1912; aged 34; honor graduate and medalist Army Medical School, 1914; who entered the Army in September, 1913; and after duty at Texas City, Texas, was ordered to Manila, where he served from March, 1916, to November, 1917, as captain and major Medical Corps; and on his return to the United States organized and equipped for overseas duty Hospital Train No. 29, at Fort Benjamin Harrison, Ind.; was on duty at Camp Sherman, Chillicothe, Ohio, in March, 1918; and was ordered to Camp Lee, Va., in April, 1918, to organize, equip and command Base Hospital No. 45, American Red Cross, Richmond, Va., and went overseas with his command, July, 1918, died in France, October 5, from illness.

John Errington Ker, Kingston, Jamaica, M.R.C.S., England, 1887; L.R.C.P., London, 1888; aged 58; chairman of the quarantine board and central board of health, Kingston, Jamaica; civil surgeon attached to General Hospitals, Nos. 2 and 3, South African Field Forces during the Boer War; who had come to New York, three weeks before, to study sanitation, died from meningitis in the Post-Graduate Hospital, New York City, October 25.

Died in the Service
in France
Lieut.-Col. A. W. Williams, M. C.,
U. S. Army, 1884-1918

Frank E. Bissel, Minneapolis; University of Wooster, Cleveland, 1869; aged 73; a veteran of the Civil War; for several terms mayor of Litchfield, Minn., and a member of the legislature from Meeker County in 1875; from 1901 to 1903 surgeon to the Soldiers' Home; and for one term surgeon of the Department of Minnesota, G. A. R.; died at his home, November 5.

Carl Lawrence Souder ⊕ Columbia City, Ind.; Northwestern University Medical School, Chicago, 1898; aged 44; who served one year in the Medical Reserve Corps, U. S. Army, and was honorably discharged, April 12, 1918, on account of physical disability; died in the Lutheran Hospital, Fort Wayne, Ind., October 25, from meningitis following an operation for sinusitis.

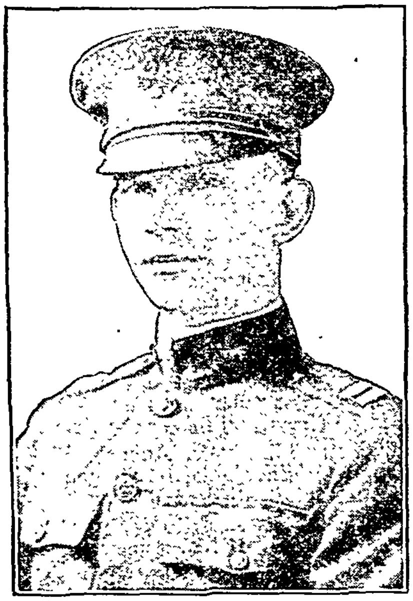
Asst. Surg. William Henry Buffum, Lieutenant, U. S. Navy ⊕ Providence, R. I., Harvard Medical School, 1902; aged 41; a specialist in pediatrics; one of the officers of the Rhode Island Naval Hospital Unit, which started overseas a few weeks ago; died in a hospital in Liverpool, England, October 13, from pneumonia following influenza.

Edward A. Whitmore ⊕ Leadville, Colo.; Gross Medical College, Denver, 1896; aged 65; for several years secretary and once president of the Lake County, Colo., Medical Society in 1915; local surgeon of the Denver and Rio Grande Railroad; city physician from 1900 to 1902; died at his home, November 8, from influenza.

Vishwas Ramual Karmarkar, Pittsburgh; University of Pennsylvania, Philadelphia, 1918; aged 27; a native of India, who was preparing for medical missionary work in his native country; an intern in the Allegheny General Hospital, Pittsburgh, died in that institution, October 10, from pneumonia following influenza.

Walter Scott Mountain, Confluence, Pa.; Philadelphia University of Medicine and Surgery, 1870; aged 80; a member of the Medical Society of the State of Pennsylvania; surgeon of U. S. Volunteers during the Civil War and thereafter a druggist of Confluence; died at his home, about October 29, from influenza.

Roy Francis Rogers, Springfield, Ill.; Rush Medical College, 1901; aged 42; a member of the Illinois State Medical Society; a member of the Aesculapian Society of the Wabash Valley, and of the staff of St. John's Hospital, Springfield; died at his home, October 21, from pneumonia following influenza.



Died in the Service
IN FRANCE
Capt. Alfred Glascock, M. C., U. S. Army, 1881-1918

Capt. Alfred Glascock, M. C., U. S. Army ⊕ Washington, D. C.; George Washington University, Washington, D. C., 1902; aged 37; formerly a member of the staff of St. Elizabeth's Hospital, Washington; while serving as psychiatrist at a base hospital in the interior of France, died from pneumonia, October 10.

Howard Kerns ⊕ Granite Falls, Minn.; University of Maryland, Baltimore, 1909; aged 42; a specialist in tuberculosis; secretary of the Yellow Medicine County Medical Society, and Camp Release District Medical Society; died at his home, October 17, from bronchopneumonia following influenza.

Newton Phineas Smith, Montville, Conn.; College of Physicians and Surgeons in the City of New York, 1882; aged 66; a member of the Connecticut State Medical Society; also a pharmacist; for thirty-five years a practitioner of Norwich; died at his home, October 3, from cerebral hemorrhage.

Elizabeth Cowan Sleight ⊕ Mount Vernon, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, 1893; aged 60; resident physician of the Auxiliary Hospital, Mount Vernon; died at her home, November 5, from pneumonia following influenza.

George Oswell Griffin, Greenville, S. C.; Medical College of Georgia, Augusta, 1901; aged 41; who entered the ministry soon after his graduation, and was pastor of the Third Presbyterian Church of Greenville; died at his home, October 9, from pneumonia following influenza.

George Cerny, St. Louis; St. Louis College of Physicians and Surgeons, 1913; aged 44; a member of the Missouri State Medical Association; and a member of the eye, nose and throat staff of Barnes Hospital, St. Louis; died at his home, September 13, from pneumonia.

George Guyer Gill ⊕ Fairview, Pa.; Jefferson Medical College, 1910; aged 35; first assistant physician at the State Hospital for the Criminal Insane, Fairview, Pa., a specialist in psychiatry; died at his home, November 4, from pneumonia following influenza.

Paul Rimer Doron, Phoenix, Ariz.; Washington University, St. Louis, 1905; aged 35; who went as a volunteer from Phoenix, to assist in the fight against influenza at Bisbee, Ariz., died about October 31, at his home, from pneumonia following influenza.

Wilhelm Rudolph Fisher ⊕ Wichita, Kan.; Northwestern University Medical School, Chicago, 1909; aged 33; a member of the staff of St. Francis' Hospital, Wichita; died in a hospital in that city, November 6, from bronchial pneumonia following influenza.

Albert Beilstein, Jr., Northampton, Pa.; University of Louisville, Ky., 1908; aged 32; a member of the Medical Society of the State of Pennsylvania; assistant physician of Dr. Haff's Hospital, Northampton; died at his home, October 27.

Lieut. Thomas Purley Johnston, M. C., U. S. Army ⊕ Mount Gilead, Ohio; Ohio State University, Columbus, 1910; aged 36; who sailed for France, September 27, died in an American Base Hospital in France, October 7, from pneumonia.

Capt. Claude Melville Campbell, M. C., U. S. Army ⊕ Decorah, Iowa; Northwestern University Medical School, Chicago, 1910; aged 33; on duty at Fort Riley, Kan.; died at Glencoe, Minn., October 23, from pneumonia following influenza.

Lewis Hasbrouck Kemble, Aspen, Colo.; University of Michigan, Ann Arbor, 1889; aged 51; surgeon of U. S. Volunteers during the Spanish-American War; died in Glenwood Springs, Colo., October 15, from heart disease.

Gardner Holway Osgood, Boston; Boston University, 1909; aged 39; roentgenologist of the Massachusetts General Hospital; died in the Evans Memorial Building of that institution, October 18, from pneumonia following influenza.

Calvin Fuller Kyte ⊕ Jersey City, N. J.; New York University, New York City, 1881; aged 68; visiting physician to X-Street Hospital, Jersey City, attending physician to Christ Hospital, Jersey City; died at his home, November 8.

John Edwin Sclanker, San Francisco; College of Physicians and Surgeons, Los Angeles; 1918; aged 34; an intern in the Southern Pacific General Hospital, San Francisco; died, October 15, from pneumonia following influenza.

Louis W. Salvin, Boston; Boston University, 1914; aged 31; a member of the Massachusetts Medical Society; died in the Massachusetts Homeopathic Hospital, Boston, September 25, from pneumonia following influenza.

Harlow Comstock McLeod, Mexico City, Mexico; College of Physicians and Surgeons in the City of New York, 1898; formerly of Batavia; was shot and killed in Mexico City, October 17, in an argument over the war.

Frederick Wheaton Baylies, Burlington, Vt.; University of Vermont, Burlington, 1897; aged 47; instructor and adjunct professor of chemistry in his alma mater for two years; died at his home, October 23, from influenza.

Lieut. Grover Carter, M. C., U. S. Army ⊕ Memphis, Tenn.; University of Tennessee, Nashville, 1917; aged 26; who had been overseas since October, 1917, serving first in England, in a base hospital, and later assigned to duty with the British Army in Flanders, and attached to the One Hundred and Twenty-First Brigade, Royal Flanders Artillery; was killed by a shell, October 16, while attending a wounded officer.

Lieut. Grover Carter, M. C., U. S. Army, 1892-1918

Richard Daingerfield Bagnall, Hampton, Va.; University of Pennsylvania, Philadelphia, 1860; aged 80; surgeon in the Confederate Service during the Civil War; died at the Dixie Hospital, Hampton, Va., November 1.

Sigurd Anton Berg, Granite Falls, Minn.; Rush Medical College, 1905; aged 38; a member of the Minnesota State Medical Association; died at his home, October 11, from pneumonia following influenza.

William Rupert Bebout, Browning, Mont.; Starling Medical College, Columbus, Ohio, 1905; aged 39; an officer of the United States Indian Service; died at his home, October 30, from pneumonia following influenza.

William I. Newberry, Smithfield, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1896; aged 47; died at his home, October 30, from pneumonia following influenza.

Warren H. Loomis, Lockport, N. Y.; Long Island College Hospital, Brooklyn, 1878; aged 63; a member of the Medical Society of the State of New York; died in the City Hospital, Lockport, October 30, from influenza.

Lieut. Frank Leonard Hammerstrand, M. C., U. S. Army ⊕ Sacred Heart, Minn.; University of Illinois, Chicago, 1909; aged 37; died in a hospital in New York City, October 26, from pneumonia following influenza.

Died in the Service
IN FRANCE
Lieut. Winfield S. Faulds, M. C., U. S. Army, 1873-1918

Lieut. Winfield Scott Faulds, M. C., U. S. Army ⊕ Roy, Mont.; Dearborn Medical College, Chicago, 1906; aged 45; commanding Camp Hospital No. 7, Thirty-Third Division, in France; died recently from pneumonia.

B. Bywaters, Van Ormy, Texas; Cincinnati Medical College, 1858; aged 80; postmaster and justice of the peace of Van Ormy for thirty-five years; died at his home, August 18, from inflammation of the bladder.

Thomas Hudson Weirich, Wellsburg, W. Va.; University of Michigan, Ann Arbor, 1873; aged 70; a member of the West Virginia State Medical Association; died at his home, November 5, from pneumonia.

Edward Elliott Morgan ⊕ North Henderson, Ill.; Keokuk Medical College, College of Physicians and Surgeons, 1905; aged 36; died at his home, November 1, from pneumonia following influenza.

Lieut. Burton Robert Carpenter, M. C., U. S. Army ⊕ Clifton, Texas; Fort Worth, Texas, School of Medicine, 1912; aged 29; ordered for duty at Fort Riley, Kan.; died at Clifton, October 25.

Guy Henry Just ⊕ Pukwana, S. D.; University of Illinois, Chicago, 1900; aged 44; chairman of the Brule County Board of Health; died at his home, November 9, from pneumonia following influenza.

Hezekiah W. Brant, Geyser, Mont.; Hahnemann Medical College, Chicago, 1888; aged 62; at one time a member of the Medical Association of Montana; died at his home, October, 31, from influenza.

James Edward Culbert, Buffalo, N. Y.; Niagara University, Buffalo, 1892; aged 52; a member of the Medical Society of the State of New York; died at his home, October 26, from pneumonia.

Nimrod Terrell Underwood, Russellville, Ala.; University of Alabama, Mobile, 1888; aged 57; a member of the Medical Association of the State of Alabama, died at his home, October 27.

Christian Zbenden, Toledo, Ohio; Homeopathic Hospital College, Cleveland, 1882; aged 72; a member of the staff of Toledo Hospital; died in that institution, October 31, from pneumonia.

Stephen Joseph Metzger ⊕ Akron, Ohio; Western Reserve University, Cleveland, 1910; aged 38; coroner of Summit County, Ohio; died at his home, November 9, from pneumonia.

Robert Coleman Kenner, Louisville, Ky.; University of Louisville, Ky., 1879; aged 59; formerly editor of the *Therapeutic Record,* died at his home, October 28, from heart disease.

Russell Tomlinson Bishop, Savannah, Ga.; Bellevue Hospital, Medical College, 1893; aged 63; for many years a practitioner of Bridgeport, Conn.; died in Savannah, October 18.

Milton C. Vest, Greensburg, Ind. (license, Indiana, 1897); aged 68; for one term coroner of Decatur County; for forty-three years a practitioner; died at his home, November 5.

Lawrence T. Carr ⊕ Martinsburg, Mo.; Keokuk, Iowa, Medical College, College of Physicians and Surgeons, 1908; aged 29; died at his home, October 24, from pneumonia.

William Joseph Fretwell, San Jose, Calif.; Missouri Medical College, St. Louis, 1888; aged 50; died at his home, November 1, from pneumonia following influenza.

Herbert Holden Thomas ⊕ Huntsville, Ala.; University of Tennessee, Nashville, 1908; aged 36; died at his home, October 7, from pneumonia following influenza.

John Homer Eudy ⊕ Deport, Texas; Memphis, Tenn., Hospital Medical College, 1913; aged 32; died at his home, October 5, from pneumonia following influenza.

Zygmond Anthony Oborski, Wilkes-Barre, Pa.; George Washington University, Washington, D. C., 1917; aged 24; died at his home, November 1, from pneumonia.

Clark S. Wood ⊕ Fort Smith, Ark.; Jefferson Medical College, 1908; aged 41; died in Sparks Hospital, Fort Smith, October 21, from pneumonia following influenza.

Lieut. Louis Robert Kratze, M. C., U. S. Army ⊕ Chicago; University of Illinois, Chicago, 1912; aged 35; died recently at Camp Crane, Allentown, Pa., from influenza.

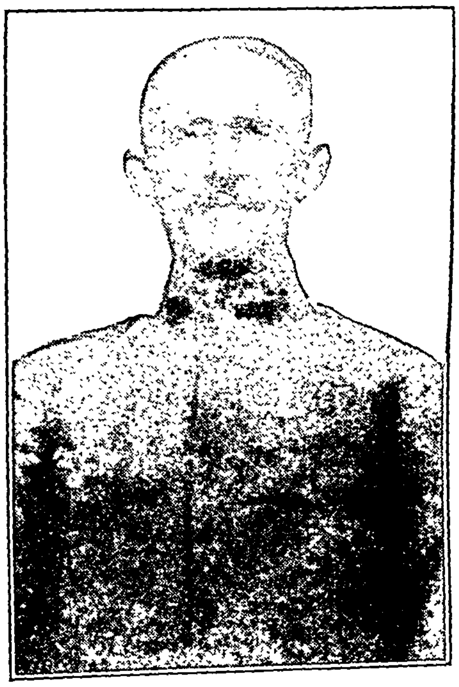
Dr. Antonio Onato, for six years surgeon on an Italian passenger steamer between America and Italy; aged 39; died at Gibraltar, in October, from influenza.

Francis M. Hyatt, Auburn, N. Y.; Hahnemann Medical College, Philadelphia, 1873; aged 71; physician to the Auburn City Hospital, died at his home, October 31.

Lafayette Reese, Afton, Wyo.; Rush Medical College, 1910; aged 38; at one time a member of the Utah State Medical Association; died at his home, October 15.

Carey Val Billingsley, Santa Ana, Calif.; California Eclectic Medical College, Los Angeles, 1914; aged 30; died at his home, about November 3, from influenza.

Robert E. Steele ⊕ Salt Lake City, Utah; University of Illinois, Chicago, 1895; aged 48; died at his home, November 4, from pneumonia following influenza.



Died in the Service
IN FRANCE
Lieut. Franklin M. Hawley, M. C., U. S. Army, 1863-1918

Lieut. Franklin Marshall Hawley, M. C., U. S. Army ⊕ Bayfield, Wis.; Drake University, Des Moines, Iowa, 1883; aged 55; on duty in a hospital in France; died, October 24, from spinal meningitis.

John Henry MacDonald, New York City; New York University, New York City, 1886; aged 60; died at his home, November 9, from heart disease.

John Frederick Brott ⊕ Doon, Iowa; Drake University, Des Moines, Iowa, 1897; aged 41; was found dead in bed from heart disease, October 30.

Jesse Judson Dearborn, Milford, N. H.; University of Kentucky, Louisville, 1905; aged 43; died at his home, October 16, from pneumonia.

Melchi Bonebrake, Taylorville, Ill.; University of Pennsylvania, Philadelphia, 1867; aged 75; died at his home, October 23, from heart disease.

Jule Conrad, Suring, Wis.; Milwaukee Medical College, 1900; aged 52; died at a hospital in Green Bay, Wis., October 27, from influenza.

H. Taylor Campbell, Nashville, Tenn.; University of Nashville, Tenn., 1875; aged 70; died at his home, November 5.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

THE KENNEDY'S TONIC PORT CASE

Booze Is Booze in Saskatchewan

When the sale of alcoholics is prohibited in a given territory, it is a notorious fact that the exploiters of those "patent medicines" whose chief and most active ingredient is alcohol, are not slow to avail themselves of the opportunity that presents itself of selling their wares to those who would use them for other than medicinal purposes. Nor is it strange that men who have previously been engaged in the liquor business, but whose business has been destroyed by prohibitory legislation, should seek to cater to their erstwhile customers by marketing liquor camouflaged as "patent medicines." Before the Dominion of Canada went "dry" some of the Canadian provinces had already enacted legislation of that type. Saskatchewan was one of them. Out of that provincial act and its aftermath, came the interesting Kennedy's Tonic Port Case.

SPANISH INFLUENZA

Of course the "patent medicine" manufacturers lost no opportunity of capitalizing the fear of the public in the present epidemic. Here are a few—just a few—advertisements reproduced in miniature. "Fortify yourself" against the Spanish Influenza by "Taking Famous Tanlac"—alcohol 16 per cent.! Make a "Gas Mask to Fight Spanish Influenza" by moistening two pieces of absorbent cotton with "Kolynos." Put a "few drops of Liquid Sozodont in a half glass of water," rinse out the mouth with the mixture, and "render pernicious germs harmless." Do you need "a powerful bulwark in preventing and treating" Spanish Influenza? Use "Benetol"! "No germ, no matter how great its strength, can live for an instant" in the presence of "Lysol"; hence, "Help Your Health Board Conquer Spanish Influenza," by the use of this preparation. "Influ-Balm Prevents Spanish Flu"; so, we are told, does "Laxative Bromo Quinine", but, in case you get the disease, you can get "relief in twenty minutes" by the use of "Men-Tho-Eze."

Kennedy's Tonic Port was booze, sold as "patent medicine." Its conflict with the law came when a bottle of the preparation was sold at a Regina drug store in November, 1917. The Saskatchewan authorities proceeded against this concern and the drug store proprietors were convicted in March, 1918, and fined $100; they thereupon appealed the case on the ground that, as they had been registered under the "Patent Medicine Act" of the Dominion government, they were thereby relieved of the necessity of complying with any provincial law, relative to the sale of "patent medicines." The judge, before whom the appeal was heard, decided against the drug concern, dismissed the appeal and amended the conviction by penalizing the drug store $500 instead of the original $100.

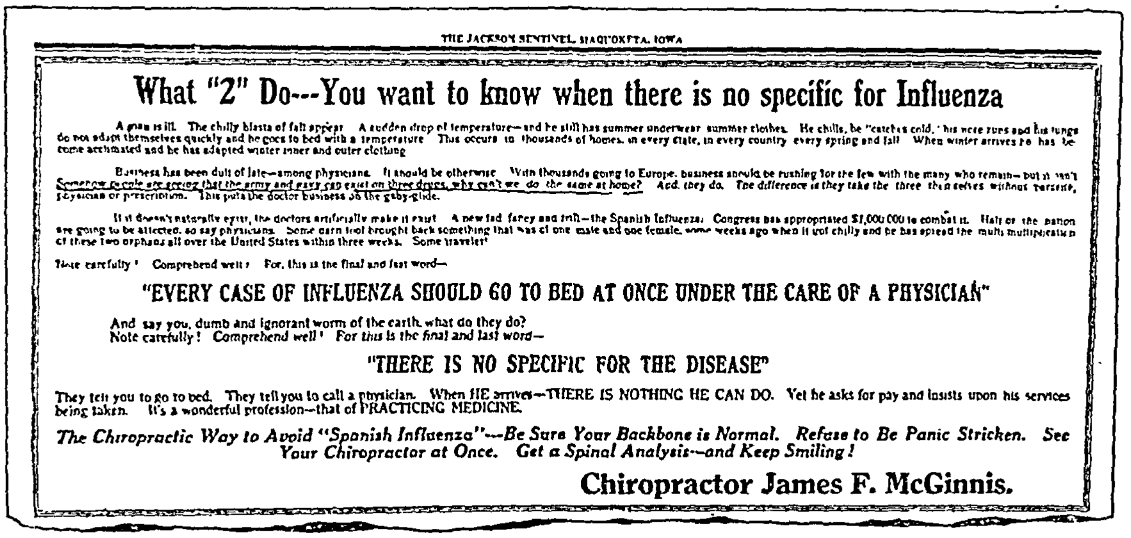
The opinion handed down by Judge Taylor of the King's Bench, before whom the appeal was tried, is an interesting document in "patent medicine" litigation, as the excerpts about to be given will show. After briefly stating the facts regarding the original conviction, and showing that the evidence established not only that a bottle of Kennedy's Tonic Port had been sold as charged but that the drug store was in the active business of selling this preparation, having, in fact, disposed of almost 700 bottles in a few months, Judge Taylor continued:

"The tonic port is a product or invention of one Joseph Kennedy. He claims to be a graduate of the British Society of Chemical Industry, and to be an expert in alcoholic chemistry. As he put it, he has spent most of a lifetime using alcohol as a solvent. For a period of 18 months, whilst the system of the licensing and sale of intoxicating liquor prevailed in Saskatchewan he was a hotel proprietor and licensee. The formula for the tonic port was, he says, conceived by him about 20 years ago, and was then put on the market by his then employers, whom he stated were a prominent manufacturing firm in the United States, under the name of 'Vitalito,' and it would appear that after the abolition of license in Saskatchewan he conceived the idea of placing this so-called tonic port on the market in Western Canada."

Of the composition of Kennedy's Tonic Port, it was admitted that the base of the preparation was ordinary port wine, to which Kennedy added a mixture which Judge

Taylor said "might best be termed a medical salad." Hyssop, dittany, Peruvian bark, orange peel, anise, coriander seed, genitan, yarrow, nutmeg, thyme, rose leaves—these were but some of the ingredients that were alleged to have been added, in quantities not disclosed, to the port wine. The amount of alcohol, however, was not unknown; it comprised about 16 per cent. by volume. The dose was a wineglassful, "equally efficacious before or after meals." The judge continued:

"As a medical salad this combination might be in great demand. The manufacturer says that it is a palatable mixture. No doubt every taste and palate should be tickled by the many different flavors. If it abhor the thyme for instance, it may find solace in the yarrow. Coriander seed would be delightfully reminiscent of home cooking, the esthetic will recognize the rose leaves. These and the six or more other ingredients in the above list added for their distinctive flavoring virtues and delightful aroma must indeed be designed to satisfy every demand. From cinchona and Peruvian bark, quinin is extracted and the manufacturer suggests that this and the gentian are valuable ingredients as cures for alcoholism. Thus there is a touch of philanthropy, though well concealed, in the salad. . . ."



THE JACKSON SENTINEL, MAQUOKETA, IOWA

What "2" Do---You want to know when there is no specific for Influenza

A man is ill. The chilly blasts of fall appear. A sudden drop of temperature—and he still has summer underwear, summer clothes. He chills, he "catches cold," his nose runs and his lungs do not adapt themselves quickly and he goes to bed with a temperature. This occurs in thousands of homes, in every state, in every country, every spring and fall. When winter arrives he has become acclimated and he has adapted winter inner and outer clothing.

Business has been dull of late—among physicians. It should be otherwise. With thousands going to Europe, business should be rushing for the few with the many who remain—but it isn't. Somehow people are seeing that the army and navy can exist on three drugs, why can't we do the same at home? And they do. The difference is they take the three themselves without nurse, physician or prescription. This puts the doctor business on the gaby-glide.

If it doesn't naturally exist, the doctors artificially make it exist. A new fad, fancy and frill—the Spanish Influenza. Congress has appropriated $1,000,000 to combat it. Half of the nation are going to be affected, so say physicians. Some darn fool brought back something that was of one male and one female, some weeks ago when it got chilly and he has spread the multi multiplication of these two orphans all over the United States within three weeks. Some traveler!

Note carefully! Comprehend well! For, this is the final and last word—

"EVERY CASE OF INFLUENZA SHOULD GO TO BED AT ONCE UNDER THE CARE OF A PHYSICIAN"

And say you, dumb and ignorant worm of the earth, what do they do?
Note carefully! *Comprehend well! For this is the final and last word—*

"THERE IS NO SPECIFIC FOR THE DISEASE"

They tell you to go to bed. They tell you to call a physician. When HE arrives—THERE IS NOTHING HE CAN DO. Yet he asks for pay and insists upon his services being taken. It's a wonderful profession—that of PRACTICING MEDICINE.

The Chiropractic Way to Avoid "Spanish Influenza"---Be Sure Your Backbone is Normal. Refuse to Be Panic Stricken. See Your Chiropractor at Once. Get a Spinal Analysis---and Keep Smiling!

Chiropractor James F. McGinnis.

"Be Sure Your Backbone is Normal"—"Get a Spinal Analysis—and Keep Smiling!" This is "The Chiropractic Way to Avoid Spanish Influenza"—Chiropractor McGinnis says so! Not, of course, that there is any such thing as influenza; it is merely "a new fad, fancy and frill." "If it doesn't naturally exist, the doctors artificially make it exist." Above all—and this is important—"See Your Chiropractor at Once." And this is the sort of stuff that the *Jackson Sentinel* of Maquoketa, Iowa, is willing, for a consideration, to spread the full width of its page, at advertising rates. It's a wonderful "profession"—Chiropractic.

"The method of manufacture, so far as the manufacturer cares to disclose the valuable secret, would not appear to interfere with the medicinal properties at least of the port wine, into which the combination is added by a method of solution into the alcohol constituent of the wine. It is still port wine, plus something indefinable. The color is that of port wine. One expert on the use of intoxicating liquors said that it tasted to him like ordinary port wine to which had been added a dash of a famous brand of 'bitters.' A number of witnesses who, in the interest of science for the most part, consumed on different occasions from a half to a whole quart bottle at what counsel termed 'a sitting,' deposed that it had a distinctly pleasing taste and produced that feeling of exhilaration which prior to the temperance legislation was recognized as intoxication. As to the aroma, the scientific tests made by counsel in the court room in his efforts to convince the provincial analyst that certain of the exhibits were not in a state of perfect preservation, convince the court that at least in that stage the aroma was strongly reminiscent of a busy bar-room."

Of course the manufacturer claimed that his "tonic port" had valuable medicinal properties and was incapable of being used as a beverage. He admitted that in 1917, the year in which Saskatchewan went "dry," the sales aggregated between $40,000 and $60,000, at the wholesale price of 75 cents a bottle. Moreover, like most "patent medicine" makers, he was able to produce at least one doctor who testified in his behalf that he had prescribed Kennedy's mixture as a "tonic." Said the judge, further:

"There is some dispute on the evidence as to whether or not there is so much quinin in the mixture that the use of it in doses beyond that prescribed on the label would be or would not be dangerous. A number of reputable witnesses swore that they consumed from half to almost a whole bottle without feeling any effects of quinin, and with the result obtainable ordinarily from drinking port wine. It is to be noted that on the label it is suggested that the use of this tonic port wine produces 'a feeling of buoyancy only attributable to perfect health.' I cannot conceive that any soberminded person suffering from any known ailment and knowing the contents of the mixture and that it contained the list of drugs which I have enumerated, would take it. It may be that the manufacturer has in some way neutralized in the mixture the effect of the different drugs contained in it. To me it seems that it is simply port wine, plus an obnoxious mixture, and I cannot overlook the fact that the secret of its manufacture lay dormant in Kennedy's mind until the abolition of the license system, and that the time was then most opportune for its manufacture, and I have no hesitation in holding that the purpose in the manufacture is simply to have put on the market port wine available for purchase without a medical prescription and to circumvent the different provincial enactments preventing the sale of intoxicating liquor. The claim that it cannot be used as a beverage is absolutely refuted in the testimony, and in the quantity sold. . . ."

"On the facts I cannot find that it contains sufficient medication or any treatment to prevent its use as an alcoholic beverage. In fact, my view is that it would have little or no sale except as an alcoholic beverage."

Correspondence

IS INFLUENZA TRANSMISSIBLE DURING THE PERIOD OF INCUBATION?

To the Editor:—Sherman Institute is a United States government school for Indian boys and girls under the United States Indian Service, at Riverside, Calif. It is a boarding school, drawing pupils from the western United States, between the ages of 8 and 20, the average being about 15. The entire expense is borne by the United States Indian Service. All of the pupils and about sixty employees are housed in dormitories on the campus, an eighth of a mile square, in an orange-growing district in the city of Riverside, 6 miles from the business center.

September 28, there arrived at the school, in care of a matron, seven Navajo boys and five girls from the San Juan Reservation at Ship Rock, N. M. En route, coming through Arizona, they encountered a woman manifestly ill with influenza. They traveled for several hours in the same sleeper with her.

Monday, September 30, C. D., one of these boys, was taken ill and sent to the school hospital on the grounds. Some intuition suggested to Mrs. Neff, the nurse in charge, that something new had come to the campus and he was immediately isolated for a possible contagion. It was evident later that he had influenza.

The following Wednesday, October 2, influenza burst on us as a storm. On that day, five boys of the party from Ship Rock came to the hospital ill with influenza and with them six other boys and three girls, making fourteen cases the first day. The second day, October 3, twenty-seven were added; October 4, forty-four; October 5, seventy. By the 8th, Tuesday, our total count was 387 cases of typical influenza of the so-called "Spanish" type. The accompanying chart gives the picture of the incidence of the disease. The last column shows how our fifty-bed hospital was filled to overflowing and four dormitory buildings became emergency hospitals in four days.

INCIDENCE OF INFLUENZA AT SHERMAN INSTITUTE, RIVERSIDE, CALIF.

	Boys	Girls	Total New Cases	Total to Date
Sept. 30 Immediately isolated	1	...	1	1
Oct. 2	11	3	14	15
Oct. 3	25	2	27	42
Oct. 4	33	11	44	86
Oct. 5	44	26	70	156
Oct. 6	36	41	77	233
Oct. 7	41	44	85	318
Oct. 8	26	43	69	387
Oct. 9	9	30	39	426
Oct. 10	6	17	23	449
Oct. 11-22	33	36	69	518
Totals	265	253	518	
Total pupils present Oct. 1, 1918	257*	313	517	
Total pneumonias to October 25				52
Total deaths to October 25, all from pneumonia				8
Total number of employees and members of families on the grounds				85
Influenza among employees and families (no pneumonias, no deaths)				34
Total influenza patients on campus				552

*Several boys came in early in October. Almost no boys escaped entirely.

Cornelius Van Zwalenburg, M.D., Riverside, Calif.

AN APPEAL FOR BELGIAN AND FRENCH PHYSICIANS

To the Editor:—I am writing on the birthday of that splendid patriot and monarch, King Albert of Belgium. I beg to remind my colleagues of the profession that now we shall be able to assist our Belgian and French colleagues who will be going back to their homes—in fact, are now going back to their homes in the territory evacuated by the barbarous Hun.

Money is especially needed now. The large number of instruments that I have acknowledged in The Journal from time to time have gone forward and more will be welcome; but, after all, the needs of these utterly destitute men can best be met by contributions in money. This money ought also to be forwarded as quickly as possible. I shall hope to send a large Christmas gift to Dr. Depage at LaPanne and the committee in Paris for the Belgian and French physicians, respectively. *Bis dat qui cito dat.*

W. W. Keen, M.D., Philadelphia.

DEMOBILIZATION OF MEDICAL OFFICERS

To the Editor:—With the big war over—for all are agreed that the signing of the armistice ended the war—although theoretically we are in a state of war until the peace conference concludes its work, a goodly portion, if not a large majority, of the more than thirty thousand physicians in service are anxious to resume their civil status. While it is recognized that there is an immense work ahead of our military establishment and while the army of occupation will require a considerable number of medical officers, it is to be hoped that the War Department will adopt a policy of at least consulting the wishes of medical officers over 40 years of age, with dependents, and dependent on their professional incomes, before continuing them on the active list. Physicians of this age may resume their civil status after an absence of a year or eighteen months practically picking up their business where they left it, whereas if they are to become a part of the army of occupation or are kept on duty in camps throughout this country for the next year or two, they will practically have to reestablish themselves; no easy matter for the physician beyond 40 years of age. The writer, always an ardent supporter of organized medicine, and appreciating the efforts of the American Medical Association to secure justice on all occasions for its members, urges The Journal to forcibly bring this matter to the attention of the Surgeon-Generals of the Army and of the Navy. While all due honor and praise should be accorded the younger members of the profession who answered their country's call, it is believed that the greater sacrifice was made by those older men who, in a time of stress, although established in practice and surrounded with young families gave up all that made life dear to them by coming into the military service. These physicians should be returned to a civilian status as rapidly as possible.

(Signed) Caduceus.

PROTECTING THE EYES IN INFLUENZA EPIDEMICS

To the Editor:—The use of an efficient mask to cover nose and mouth has been thoroughly well exploited. Notes are beginning to come in now of nurses and others contracting influenza despite the use of masks and washing of hands. The fact that the eyes are exposed to mouth spray has been generally overlooked, and little reference, if any, has been made to the necessity of wearing some protection for the eyes. It is obvious that the eyes may be directly infected, or that the organisms falling on the eyes may be carried by the tear ducts to the nose, and therefore to the throat and mouth.

I have seen an instance in which diphtheria was contracted by a most careful physician who wore a mask and washed his hands, the fact being that the patient from whom he was taking a culture coughed directly into his eyes. He did not contract diphtheria of the eye, but of the throat. His exposure was limited to one evening when he relieved the regular man in charge of a diphtheria ward. It is well known that in the pneumonic form of the bubonic plague the necessity of precautions to cover the eyes as well as the nose and mouth is thoroughly well established.

H. W. Hill, M.D., St. Paul
Executive Secretary, Minnesota Public Health Association.

DISCONTINUANCE OF COMPATIBILITY TEST IN SERUM TREATMENT

To the Editor:—Numerous inquiries concerning compatibility tests, etc., have led us to offer the following suggestions for informal publication:

After consultation with reputable laboratory workers in Boston and New York, it was decided to discontinue the compatibility test of the donor's serum with the recipient's corpuscles. It would seem reasonable to believe that in all probability the donor's serum is so rapidly diffused and diluted in the blood stream that hemolysis and agglutination of a dangerous nature will not follow, whereas untoward reactions might result from introducing cells into a concentrated serum as in transfusion. Moreover, we have repeatedly given so-called "incompatible serums" to patients without the slightest untoward symptoms.

Further experience has led us to pool the serum from our donors. This simplifies the preparation and the administration of serum, and apparently gives more uniform results.

One of us, in a recent visit to New York, found physicians using 25 c.c. amounts of serum. Needless to say, in view of the serum therapy of "type" pneumonias, such dosage would hardly be expected to produce results. Our experience in the treatment of eighty cases points to at least 100 c.c., and as high as 200 c.c. of serum every eight hours, till results are obtained.

May we also suggest that the clinician must always be on the alert for a lobar pneumonia, due to a type pneumococcus, for which type serum might be useful.

L. W. McGuire, M.D., and
W. R. Redden, M.D., Chelsea, Mass.
Lieutenant-Commander and Lieutenant, Junior Grade, respectively, U. S. Navy.

CONTROL OF THE COUGH IN INFLUENZA

To the Editor:—For the past month I have been on epidemic duty with the United States Public Health Service. Most of the cases that I have seen that have developed pneumonia have been complicated with a most rebellious cough. This has been so common in my own experience and with those with whom I have discussed this epidemic that it has occurred to me that this cough might be one of the causative factors of the pneumonia, either by producing trauma in some part of the respiratory mechanism which acts as an infection atrium, or by so lessening the resistance of the patient through loss of sleep, pain and exertion that he readily picks up the pulmonary infection.

The cough at first seems to be only irritative, for the patient expectorates but little; usually, however, after coughing almost incessantly for two or three days, he begins to spit up fresh blood; in another twenty-four or forty-eight hours this has changed to a typical "prune juice" sputum, with a fever of from 103 to 104 and the physical findings of bronchopneumonia.

In all my cases the cough was controlled completely with diacetylmorphin, from $\frac{1}{12}$ to $\frac{1}{6}$ grain, as circumstances may require. I am sure that a cough that is causing a patient great pain or interfering with sleep should certainly be controlled.

This may be regarded as quite commonplace, but I have seen so many cases in which the cough had not been controlled that perhaps a reminder of a commonplace might prove a decided benefit to the patient.

In this connection let me add that I see many physicians using heavy cough syrups with but little effect on the cough and usually producing nausea and gastric irritation, thereby making proper feeding impossible. Diacetylmorphin in tablet triturate form produces no such side-effects and is always most effective in the control of the cough.

Harry H. Myers, M.D., Shelby, Ohio.

"ATTITUDE OF CHRISTIAN SCIENTISTS IN THE PRESENT EPIDEMIC OF INFLUENZA"

To the Editor:—"The churches in Boston were not ordered closed by health authorities—merely requested," writes Walter H. Van Zwoll to The Journal, November 9. What were the Eddyites waiting for? A club? Mr. Hoover's early requests for food conservation were accepted at once by a large proportion of the American people. The more definite regulations and prohibitions did not appear until some time later. This cheerful compliance was a source of marvel to the New York correspondent of *L'Illustration*, Paris, who thereupon made the flattering comment, "I have said not once but twenty times that this is the best disciplined nation on the face of the earth—a request from the top is all that is necessary."

According to Carl Ackerman, the Eddyites in Berlin also believed in food conservation, but for an altogether different purpose. Immediately after the outbreak of war they laid by in store provisions in such quantities as to cause comment. Evidently "The Lord will provide" was construed as implying that He helps those who help themselves. Even that cheapest form of altruism which expresses itself liberally in assurances that all is well was for the moment possibly adjourned in the hurry to respond to the motivation of the main chance.

C. B. Burr, M.D., Flint, Mich.

A SIMPLE BLOOD STAIN

To the Editor:—Being dependent on a rather uncertain source for distilled water suitable for use with Wright's or Jenner's blood stains, I have finally found a method with which both "power house" distilled water and tap water may be used with success. Neither waters are filtered before use.

Webster's "Diagnostic Methods," Edition 5, and Simon's "Clinical Diagnosis," Edition 9, give different methods of preparing and using Pappenheim's panoptic stain, and by combining parts of each formula and method I have hit on a stain that is quick, clean and reliable (so far) for blood.

From Simon I make up Giemsa stain thus:

Azur II-eosin	3.0 gm.
Azur II	0.8 gm.
Glycerin, U. S. P. IX	125.0 c.c.
Methyl alcohol, acetone free	375.0 c.c.

Dyes are ground up in the alcohol and added to the glycerin.

To 150 c.c. of the foregoing solution I add 100 c.c. of Jenner's stain (1.5:1) and use thus:

I fix blood smears by immersion in this stain in a Coplin staining jar for one minute, and transfer directly, without shaking or washing, to a Coplin jar containing water, and after from two to five minutes' immersion wash briskly for a few seconds and stand the slide on its end to dry. Blotting is admissible.

Specimens are clear of precipitates, and when distilled water is used a characteristic panoptic picture is shown. Both single and double solutions seem to be stable, the Jenner stain that I use having been compounded seven months ago.

No originality is claimed; but if this method helps some one on a hurry-up job of staining, I shall rest contented.

Frank W. Lacy, Fort Lyon, Colo.

DIPLOCOCCI AS A FURTHER STAGE OF INFLUENZA BACILLI

To the Editor:—I wish to address an inquiry to clinicians and laboratory workers in reference to a conclusion based on studies of influenza. Has it occurred to any worker to associate the gram-positive diplococcus usually found intracellularly and extracellularly with Peiffer's bacilli as a further stage of the bacillus? My investigations have led me to a tentative conclusion that such is the case, analogous to the relationship of the fusiform bacilli and spirochetes in Vincent's angina.

John Lear, M.D., Allentown, Pa.
Pathologist, Allentown Hospital Association.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

FOLLICULAR OPENING IN EXTERNAL EAR A REMNANT OF BRANCHIAL CLEFT

To the Editor:—A few times I have noted, in adults and in children, a structure that I have never seen named nor described. It is a crypt or follicle or glandular opening in front of the upper portion of the external ear. It has the appearance that a pin prick would have in an inelastic material. In some cases a thick secretion issues from it. It is sometimes bilateral, sometimes unilateral. I presume it is a vestigial organ, but would like to know more about it.

James W. Walker, M.D., Chicago.

Answer.—The condition which is referred to is spoken of in the literature as fistula auris congenita, and is a remnant of the first or second branchial cleft. The fistula is due to an incomplete closure of one of these clefts. There is no connection between the fistula and the middle ear nor with the development of the external meatus. Politzer says it is "a short blind sac lined with epithelium, secreting a milky fluid." The external orifice is situated about one centimeter above the tragus, and one to two centimeters before the helix. If the opening of the fistula becomes occluded the secretion of the sac is retained and it gives rise to a cystic swelling (branchial cyst). The contained fluid may become infected and form pus. Politzer has never observed a bilateral case. The fistula may be accompanied by other anomalies of the ear such as congenital deformities of the external ear.

As a rule, fistula auris congenita does not call for any treatment. If there is a retention cyst or an abscess due to a collection of degenerate epithelial matter, or if there is a foreign body which has gained entrance to the external orifice, the fistulous tract may be laid open and the lining epithelium curetted away.

Maryland Homeopathic Report

Dr. O. N. Duvall, secretary of the Maryland Homeopathic Board of Medical Examiners, reports that on Jan. 3, 1918, a graduate of the Hahnemann Medical College and Hospital of Philadelphia in 1917 was examined and passed, on July 6, 1918, two 1918 graduates from the same school were examined and passed, and on March 18, 1918, a graduate of the Detroit Homeopathic College in 1901 was licensed through reciprocity with Michigan.

Rhode Island October Examination

Dr. B. U. Richards, secretary of the Rhode Island State Board of Health, reports the practical and written examination held at Providence, Oct. 3-4, 1918. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Of the 5 candidates examined, 4 passed and 1 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surgery	(1916)	87.5
Harvard University	(1915)	83.6
Tufts College Medical School	(1917)	85.8
University of Vermont	(1918)	93.5
FAILED		
College of Physicians and Surgeons, Boston	(1910)	78.4

Texas Reciprocity Report

Dr. M. F. Bettencourt, secretary of the Texas State Board of Medical Examiners, reports that 43 candidates, including 6 osteopaths, were licensed through reciprocity since Jan. 1, 1918. Fourteen candidates, including 2 osteopaths, were granted verification licenses. The following colleges were represented:

College	Year Grad.	Reciprocity with
LICENSED THROUGH RECIPROCITY		
University of Arkansas	(1915)	Arkansas
George Washington University	(1913)	Dist. Columbia
Atlanta College of Physicians and Surgeons	(1902)	Oklahoma

Book Notices

Surgical and War Nursing. By A. H. Barkley, M.D., M.C., F.A.C.S., Lecturer at Good Samaritan Hospital Training School for Nurses. Cloth. Price, $1.75. Pp. 208, with 79 illustrations. St. Louis: C. V. Mosby Company, 1918.

A Textbook of Physiology for Nurses. By William Gay Christian, M.D., Professor of Anatomy, Medical College of Virginia, and Charles C. Haskell, M.A., M.D., Professor of Physiology and Pharmacology, Medical College of Virginia. Cloth. Price, $1.75. Pp. 168, with illustrations. St. Louis: C. V. Mosby Company, 1918.

Nursing in Diseases of Children. By Carl G. Leo-Wolf, M.D., Chief of Clinic for Sick Babies and Children for the Health Department of the City of Buffalo, N. Y. Cloth. Price, $2.50. Pp. 314, with 72 illustrations. St. Louis: C. V. Mosby Company, 1918.

Hygiene for Nurses. By Nolie Mumey, M.D., Lecturer in Hygiene, Chemistry, and Bacteriology, Logan H. Roots Memorial (City Hospital) Training School. Cloth. Price, $1.25. Pp. 160, with 75 illustrations. St. Louis: C. V. Mosby Company, 1918.

Essentials of Dietetics. A Textbook for Nurses. By Maude A. Perry, B.S. Cloth. Price, $1.25. Pp. 159. St. Louis: C. V. Mosby Company, 1918.

These books for nurses have been issued by the publisher in a uniform size and binding.

Dr. Barkley's experience in war nursing is based on service in the Spanish-American War and intimate acquaintance with eminent surgeons recently returned from the European battlefields. All of the illustrations of instruments were lent by a manufacturing house in Cincinnati. This book cannot be said to be an exceptional work.

Christian-Haskell's book on physiology is exceedingly brief, and at that probably not so brief as most nurses would have it. The chapter on the nervous system is quite technical. The others are good.

Leo-Wolf's book is very practical, quite complete and written in simple, direct language. After each chapter is a series of questions for review.

Mumey's book gives the merest outline of hygiene for nurses, and is extremely superficial.

Perry's is a solid work, giving the essentials of dietetics for nurses and following in many respects the book by Strouse and Perry on food for the sick. This book will be of distinct help to nurses.

Diseases of the Male Urethra, Including Impotence and Sterility. By Irvin S. Koll, B.S., M.D., F.A.C.S., Professor of Genito-Urinary Diseases, Post-Graduate Medical School and Hospital. Cloth. Price, $3 net. Pp. 151, with 123 illustrations. Philadelphia: W. B. Saunders Company, 1918.

After a short recapitulation of the anatomy of the male urethra and its appendages, the author gives a brief abstract of the history of gonorrhea. This is followed by a summary of the modern views on the bacteriology and pathology of gonorrheal urethritis. These chapters while a trifle too concise, contain all the leading points. In his presentation of the treatment of gonorrhea the author forestalls the opposition that most of his confrères probably will offer to some of his therapeutic suggestions by emphasizing that they represent his personal views derived from his individual experience. The notes on the endoscopic findings are the result of careful work, and are accompanied by excellent colored pictures. This cannot be said about the description and illustrations concerning the operations undertaken for the relief of the complications and pathologic sequelae of gonorrheal urethritis. The closing chapters deal along the usual lines with sexual impotence and sterility in the male.

Medicolegal

Jurisdiction Over Recruits Afflicted with Disease

(In re Traina (U. S.), 248 Fed. R. 1004)

The United States District Court, Eastern District of New York, in denying an application for a writ of habeas corpus, says that relator Traina applied for the writ, directed to the commanding officer at Camp Upton, who, it was said, held the relator without authority, in that the relator claimed to be afflicted with a disease which he alleged made necessary his discharge from further Army service. He based the application for habeas corpus, in the first place, on the provisions of the selective service act and the rules promulgated thereunder, which direct rejection and discharge from military service of men with diseases and organic troubles which he claimed were less severe than those from which he suffered. But it must be held that this court has no jurisdiction either to consider the physical or medical standards by which persons otherwise eligible are to be judged either for admission to or discharge from the National Army. Such matters are clearly within the jurisdiction of the local and district boards or the Army authorities themselves.

The relator also claimed that the general provisions of Section 1116 of the Revised Statutes of the United States, requiring recruits to be "effective and able-bodied," made it illegal to retain a man suffering from such physical disability in the military forces of the United States, and that this court had power, on a writ of habeas corpus, to enforce the discharge of any one so afflicted. But no authority was cited from which it could be inferred that the court had such general power over the military forces of the United States. Any determination that a person should no longer be retained in the Army must be sought at the hands of the Army itself, even if it be evident that refusal to discharge would be illegal (Section 1342, as amended by Act of Aug. 29, 1916).

More than this, if the decision by the military authorities is adverse to the applicant, the court has no jurisdiction, if that decision is within the jurisdiction of the military authorities to determine. It has always been held, and is believed to be the law, that all such jurisdiction is vested in the military authorities, and that they have complete control and discipline over a man until they see fit to discharge him, if he has been lawfully brought into the service, and if the military authorities have not gone outside of the jurisdiction given them by statute, in administering the affairs of their own commands.

Requiring Drafted Person to Submit to Operation

(De Genaro v. Johnson (U. S.), 249 Fed. R. 504)

The United States District Court, Eastern District of New York, says that relator De Genaro, who applied for a writ of habeas corpus, was in the National Army at Camp Upton. He claimed to be suffering from hernia, and raised the contention that both the local board and the examining officers of the Army at Camp Upton were aware of this physical disability, even though the examination by the medical examiners of the local board, and the further examination at Camp Upton, did not result in his rejection for physical disability. In general, the case was like that of Traina, 248 Fed. R. 1004, in which it was held that the selective service law and sections 1116 and 1342 of the Revised Statutes of the United States make the decision of the examining board final so far as an application to the court by way of habeas corpus is concerned. But relator De Genaro raised a further point, as to which no decision seems to have been rendered. He alleged that the physical examination at Camp Upton resulted in his being ordered to undergo an operation to relieve him from the hernia complained of. He refused, and still refused, to submit to this operation, and in consequence of this refusal applied to this court for release through a writ of habeas corpus, alleging that the Army had no authority to hold him, inasmuch as they could not compel him to submit to the operation, and as he was therefore within the class of persons who are entitled, on physical examination, to be discharged from further military service.

It is evident that the unwillingness of the relator to submit to an operation could be used by a person so disposed as an excuse for further escaping military service, even though he might be willing and anxious to have the operation performed under ordinary circumstances. In any such case the court should not act directly in contravention of the provisions of the selective draft law, by which the findings of the boards and their examiners are final on such questions. The ordinary provisions of the military law then apply, and must be construed in connection with the laws under which the National Army has been created; but if a person were admittedly found to be physically disabled, by an examining board of the Army, and if the Army authorities should refuse to discharge him, for purely arbitrary or disciplinary reasons, the courts have no authority to take testimony, examine into the man's physical condition, on a hearing, and discharge him as held without authority of law, even if the facts appeared as he alleged. The writ must be dismissed, and the relator remanded.

Unconstitutional Laws Providing for Sterilization

(In re Thomson et al. (N. Y.), 169 N. Y. Supp. 638. Haynes v. Lapeer Circuit Judge (Mich.), 166 N. W. R. 938)

The Supreme Court of New York, Special Term, Albany County, in re *Thomson and others,* composing the board of examiners of feebleminded criminals and other defectives, reverses the board on its determination to perform vasectomy on one Frank Osborn, an inmate of the Rome Custodial Asylum, 22 years of age, strong physically, who had been an inmate of that institution for several years, and who was in the class known as feebleminded, and the court grants him an injunction restraining the carrying out of the determination of the board, because the court holds that Chapter 445 of the Laws of New York of 1912, amending the Public Health Law by adding Article 19 thereto, in relation to operations for the prevention of procreation, is unconstitutional. The court says, among other things, Can it be said that the law can direct the physical mutilation of the bodies of those who are in the state's care, and not be concerned with the same class of persons who are in the world at large? It seems clear that Frank Osborn is not given the equal protection of the laws, having in mind many others situated as he is who are not within the walls of a public institution, to which equal protection he is entitled with them. There is afforded to the young man similarly situated as to his physical and mental make-up, who is cared for by his parents in his own home, whose sexual tendencies and capacity may be the same as Osborn's, the protection of the law, which makes it a misdemeanor for any person to assist or take part in the operation of vasectomy on such a subject, while Frank Osborn, because he is an inmate of a state hospital, is not only not protected, but he is subject to such operation without his consent when determination is reached by the board created under this statute. The state has power, many times sustained by the courts, to protect the health, morals and welfare of the people, but such protection cannot be afforded unless it applies to all alike.

The Supreme Court of Michigan, in the case of *Haynes,* Superintendent of Michigan Home and Training School, v. *Lapeer Circuit Judge,* denies the plaintiff a writ of mandamus to review and reverse an order of the circuit court sustaining an order of the probate judge, refusing to entertain jurisdiction on the plaintiff's petition for a hearing to determine the question of the sanity of an alleged incompetent named Nora Reynolds, confined in the Michigan Home and Training School at Lapeer, and the necessity of performing on her the operation of salpingectomy, under the provisions of Act 34 of the Public Acts of 1913, on the ground that the act is unconstitutional. The court says that the only question argued or raised in this proceeding against the validity of the law being that it was capricious and discriminating class legislation, there was no occasion to dwell or pass on any suggested underlying medicolegal questions to which the indicated purpose of the law points and which within constitutional limits are for legislative rather than judicial consideration. The court is constrained to concur in the opinion of the circuit judge that this law as framed does not afford, in its scope, those affected by it that equal protection under the laws guaranteed by the constitution, and so limits the class of defectives covered by its provisions as to be clearly class legislation without substantial distinction within constitutional inhibition. What logical connection with the object sought by this enactment has a classification which carves a class out of a class and applies the proposed curative treatment, which it is found the public weal demands and justifies, only to those of the type requiring such exclusive legislation who, by reason of their sequestration under public control, are presumably helpless to work on those now in being or posterity the mischief which the law is framed to eliminate? In this enactment the legislature selected out of what might be termed a natural class of defective and incompetent persons only those already under public restraint, leaving immune from its operation all others of like kind to whom the reason for the legislative remedy is normally and equally, at least, applicable, extending immunities and privileges to the latter which are denied to the former.

Period Employer Must Furnish Medical Services

(In re McKenna (Maine), 103 Atl. R. 69)

The Supreme Judicial Court of Maine holds that in a case in which a claimant under the workmen's compensation act received her injury on September 11, and the industrial accident commission found that "disability" began on September 18, the commission erred in holding that the date of the accident would be considered as of September 18, and ordering that medical bills, not exceeding $30, covering the fourteen days following September 18, be paid by the employer. The court says that the plain language of the statute restricts the period during which the employer must furnish medical services, etc., to the first two weeks "after the injury," and, while the act is remedial and to be broadly construed, the court finds no authority for the substitution for the word used in the statute of another term used in the same statute with a clearly different meaning. If it is desirable to change the period during which medical services shall be furnished, or to extend the powers of the commission in that regard, legislative action should be had, as was done in Massachusetts. Nor does the court consider that such a rule as that adopted by the commission is necessary to carry out the legislative intent. Its evident purpose was to allow no compensation in the nature of wages for the first two weeks after the injury, at least when the incapacity is partial, and during those two weeks to allow as compensation to the injured employee his medical expenses, to the end that the latter might not for reason of economy delay seeking medical advice, even though the injury might be slight and not immediately incapacitating.

Competent to Give Opinion on Mental Condition

(Monahan et al. v. Roderick et al. (Iowa), 166 N. W. R. 625)

The Supreme Court of Iowa holds that the fact that it appeared in a contest over a will that the physician who had attended the testatrix was not a specialist in mental diseases would not necessarily destroy his expert character, and did not disqualify him from expressing his opinion on the mental condition of the testatrix. The court says that the boundaries of the field of expert knowledge are somewhat indefinite. There are varying degrees also of expert knowledge on any subject. A regular practicing physician is usually regarded as expert, at least to some extent and for some purposes. The court sees no reason to say that he is not qualified as such to give an opinion as to the feebleminded condition of the patient under his care. It was unimportant that the question in this case asked the opinion of the witness whether the mind of the testatrix was sound, and did not ask whether it was unsound, although the trial court seemed to think that the first form of question was proper while it would not have been proper to ask the witness for an opinion whether the mind of the testatrix was unsound.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Eighth Annual Session, held at Philadelphia, Sept. 23-26, 1918

(Continued from page 1691)

Absence of Clinical Symptoms During Preperforated Stage of Duodenal Ulcers

Dr. Levi J. Hammond, Philadelphia: Of fourteen patients operated on during the past two years at the Methodist Episcopal Hospital for perforated duodenal ulcers, not even the frequent complaint of digestive disorder is noted in the histories as occurring during their latent period. In none of them was complaint made of such symptoms as paroxysmal pain, localized tenderness, vomiting, hematemesis, or hyperacidity of the gastric juices. None of the patients were chlorotic or anemic and there was no history of burns or scalds or other serious accidents that could have been a factor in etiology. In most instances the perforations occurred while the patients were at their usual occupations. In one, perforation occurred during the middle of the night while the man was asleep in his bed.

DISCUSSION

Dr. M. Behrend, Philadelphia: It is my experience that many cases of perforation give no symptoms. These cases usually occur in men. They are working and are suddenly seized with terrific pain that overcomes them and the perforation has occurred. On close questioning of these patients a history of gastric disturbance, commonly called "indigestion," is usually received.

Dr. John J. Gilbride, Philadelphia: It is not uncommon to have cases of perforation without any preperforative symptoms. Vomiting and hemoptysis are rare in duodenal ulcer. About the only symptom one could tie to would be pain. Hyperacidity is not at all diagnostic. Finding occult blood in the stool may be of value .

Dr. Donald Guthrie, Sayre, Pa.: I have endeavored to find out whether there is any change in the symptoms during which the perforation occurred and the symptoms that all the patients complain of, but even by asking the most direct leading questions it is impossible to elicit any early ulcer history.

Postoperative Sequelae of Acute Appendicitis

Dr. John B. Deaver, Philadelphia: In 1,700 operations for acute appendicitis there were sixty-six deaths, a mortality of 3.7 per cent. The series included all cases of acute appendicitis with and without preoperative complications directly due to the condition of the appendix or to the involvement of other viscera. Of the complications, fecal fistula occurred in forty-two cases, secondary abscess in thirty and intestinal obstruction in twenty-seven cases. An analysis of the cases of obstruction shows that fully 70 per cent. required drainage at the original operation. There is no doubt that in every case of acute appendicitis requiring drainage operation was delayed beyond the most favorable moment. In the prevention of surgical complications there is nothing more important than to forestall the formation of pus within the peritoneal cavity. A large number of these cases would not have developed adhesions and consequent obstruction if the original appendicular disease had been treated early and no drainage had been required.

DISCUSSION

Dr. H. J. Donaldson, Williamsport: To the post operative sequelae mentioned I wish to add acute renal insufficiency, acute gastric dilatation, and hemorrhage from erosion of drainage tubes. Of the fecal fistula group my experience leads me to believe that the causes are gangrene of the base of the appendix involving some area of the cecum, failure to remove the appendix, erosion of the intestines by the drain and ulcer of cecum due to thrombosis of the blood supply, or extension of gangrenous process. To overcome this occurrence, it has been my habit always to remove the appendix, to free the adhesions to admit of invagination of the cecal wall if gangrenous, and to effect an early change in the position of my drainage to prevent pressure on the bowel or large blood vessels and other important structures. One of the greatest lessons I ever had in drainage tube accidents was the sudden death of a man rapidly recovering from a general peritonitis, who on the seventh day developed a hemorrhage from his iliac artery and died in a few minutes.

Wounds of the Joints, with Especial Reference to Splintage

Lieut.-Col. Robert B. Osgood, M. C., U. S. Army, Boston: in any serious engagement, we may expect nearly one half of the severe injuries to involve the bones and joints and among these, the phenomenon of shock is very common. Shock is of first concern and infection is a close second. Perhaps the most common cause of shock is trauma. Infection feeds first on traumatized tissue. Transport must always add trauma to trauma already existing. It becomes the first duty of the surgeon to lessen this trauma by every possible means. Proper splinting materially lessens it. Therefore, proper splinting becomes of first concern. The first essential in good splinting for transport is the comfort of the wounded man. If the splint gives him ease from his wound pain and does not add another discomfort, the first requisite is met. The splints must also fulfil the mechanical purposes for which they are applied. The design of the splints must be simple and their weight light, in order that they may be manufactured in large quantities and be transported easily far up the line to the battalion aid posts. For fractures of the long bones and certain joint injuries it is extremely desirable that they embody the two principles of fixation and traction: Fixation, to protect the injured structures and to retain proper alinement after the alinement has been secured; traction, to bring about muscular relaxation with the object of diminishing pain by inhibiting involuntary contraction, which also results in malposition.

DISCUSSION

Capt. Roades Fayerweather, M. C., U. S. Army, Washington, D. C.: The importance of splinting cannot be emphasized too much. It is the first form of specialized treatment that the soldier with a bad fracture receives, and frequently very soon, if not immediately, after his injury. This treatment must frequently be applied by men who have had no experience in medical or surgical work, that is by the corps men, therefore, these methods should be simple and capable of routine application. Every surgeon in the expeditionary force must be his own orthopedic surgeon. It is impossible for the orthopedic surgeon to be in attendance on all these cases; hence the surgeon handling these cases must look on them with an orthopedic eye. He must look to the functional result; he must learn to use these splints and he can do so very easily because of their simplicity.

Lieut.-Col. Robert B. Osgood, Boston: In the aftermath of cases coming through England, 30 to 50 per cent. of the cases of deformity filling the military hospitals represents the preventable deformities.

Combating Septicemia with Arsphenamin

Dr. Samuel R. Haythorn, Pittsburgh: Arsphenamin was administered in twenty-nine cases of proved septicemia with seventeen recoveries and twelve deaths. The treatment proved beneficial when used early in septicemias if they were associated with primary foci which were easily accessible to surgical interference. In endocarditis and other conditions in which secondary localizations had become firmly established, arsphenamin was disappointing because it did not affect the localized lesions on the heart valve but appeared to be effective only in the blood stream.

DISCUSSION

Dr. Harold A. Miller, Pittsburgh: We have used arsphenamin in fourteen cases. In none did we get any untoward symptoms which we could attribute to the arsphenamin. We have found no contraindications in puerperal sepsis for the use of arsphenamin that are not also contraindications in syphilis or other diseases. In every instance but one in which we gave the arsphenamin we were able to demonstrate a negative blood culture. The patient was a woman with a vegetative endocarditis. In every instance in which the remedy was given before there was a localized area of infection there was a temperature drop in the way of crisis within twenty-four hours. A daily leukocyte count was taken to determine the indication for repeating the dose. In the very virulent cases the leukocyte count was very low in comparison with the illness of the patient. Following the administration, the leukocyte count would increase to 32,000 within from twenty-four to forty-eight hours. In our series one patient died of streptococcic pneumonia, one of multiple abscess of the kidney and one of peritonitis. In our ultimate results we found no untoward effects.

Dr. Grover C. Weil, Pittsburgh: In a case of staphylococcic septicemia resulting from a compound fracture following considerable traumatism of the wounded surface with fluctuation of temperature between normal and 101 F. for five weeks, the temperature was normal in five days following the administration of arsphenamin and five days later the staphylococci had disappeared from the blood. The man subsequently regained his weight, and in three weeks following the first administration of the arsphenamin there was almost complete union of bone.

Dr. S. R. Haythorn, Pittsburgh: Following the administration of arsphenamin, an increase in the number of leukocytes was a constant finding. The importance of repeated blood cultures should be emphasized, particularly in the presence of persistent fluctuating temperature. The results in the treatment of endocarditis were discouraging, but Zinsser observes that endocarditis is a secondary infection of the heart valves, and that the vegetations on them act as localizations, from which bacteria may be poured into the blood stream continually. While not arguing that arsphenamin is an ideal drug for the treatment of septicemia, we hope by its careful use to reduce the mortality in blood stream infections.

Physical Examination in the Diagnosis of Early Pulmonary Tuberculosis

Dr. Louis V. Hamman, Baltimore: When 100 men come before us for examination, we know that at least seventy have pulmonary tuberculosis. Of the seventy with signs of pulmonary change, only four or five will develop the disease. Nothing can be more important than to distinguish between tuberculous infection and tuberculous disease. It is impossible to put an absolute value on the physical examination in the diagnosis of pulmonary tuberculosis. It really takes its value from the relations of all the other associated clinical facts. One exception to this statement is in favor of râles. When definite moist râles are limited to an apex this is an almost absolute indication of pulmonary tuberculosis, provided the general evidence points to the presence of the disease. This conclusion may be drawn safely even though at the time of examination the usual symptoms of tuberculous disease are absent. In this important emphasis I mean definite unmistakable fine moist sounds heard at an apex, and not the many adventitious sounds which so frequently puzzle the adept and mislead the novice. So far as tuberculosis is concerned in the war problem, not only the obviously tuberculous should be excluded from active service, but those likely to develop the disease from exposure incident to camp life.

DISCUSSION

Dr. Elmer H. Funk, Philadelphia: Physical signs are valuable only as emphasized by the consideration of history and symptoms. Far more important is the determination whether the disease is clinically active or clinically inactive. We must learn what from the roentgen ray point of view constitutes a normal chest.

Dr. Charles H. Miner, Wilkes-Barre: The most important question is the relation between the extent of the pulmonary changes not due to active disease and the probability of developing active disease under conditions of unusual exposure. Nearly 3 per cent. of 5,945 measles patients have developed tuberculosis. There are many occupations with less exposure and in which the risks to a tuberculous individual are much less than in the trenches.

Dr. Thomas McCrae, Philadelphia: The view expressed by some that the man in the Army is not much exposed to infection is of doubtful accuracy. Regarding pensions, if the Army accepts a man who later is found to have tuberculosis, it seems reasonable that he should be pensioned by the government. I would put as the first consideration of useful points in diagnosis the fact that suspicion is aroused. It is then our business to exclude the possibility, rather than to take the view, for example, that the condition is nothing but bronchitis.

Essential Hypertension

Dr. Herman O. Mosenthal, Baltimore: It is important to recognize this disease, which thus far is characterized by the presence of only one symptom, namely, hypertension. There is no pathologic physiology of the organism of which we are aware that brings about hypertension. It exists in a great number of individuals and usually results in severe lesions of the heart, brain or kidney which cause death. The diagnosis can be made with certainty only when the tests for renal function are available. Treatment involves some of the most intricate questions in metabolism. The effective treatment is prophylaxis. Mental and physical rest seem to constitute the main element in the successful treatment. A diet regulating quantity rather than quality that the heart efficiency may not be interfered with by the distended stomach and that obesity may be forestalled or diminished, accomplishes as great results as are possible through food control. Attention to hygienic instructions may often prolong life to a considerable degree.

DISCUSSION

Dr. James M. Anders, Philadelphia: Essential hypertension is of great importance because these cases usually terminate in serious cerebral, arterial, cardiac and renal developments. That very fact should make us reserved in classifying the condition as a separate disease entity. The condition, in my experience, is by no means as frequent as certain writers would have us believe. Clinicians have failed to exclude cases in which some cause of hypertension could have been found with sufficiently thorough investigation. We are not justified in making a diagnosis without resort to the tests for renal function. Such tests have revealed insidious developments in the kidney structure, showing that cases of apparent essential hypertension could not be regarded as such. Many of the cases of persistent hypertension in middle aged men in active business given to the pleasures of the table and to excesses in alcohol and tobacco, in my experience, yield to treatment, prolonged rest and correction of the habits of the patient, and should not be classified as belonging to this clinical group of true essential hypertension.

Dr. Ross V. Patterson, Philadelphia: An important group of cases of hypertension must be distinguished from the much more common forms due to renal sclerosis, a condition in which the hypertension is the primary change, and in which the changes in arteries and slight changes in kidneys are secondary but with decrease of hypertrophy of the heart. The difference in clinical course is important; also the difference in management, prognosis and treatment. When sclerosis of the kidney is a primary factor renal functional tests are essential to diagnosis of hypertension.

Dr. Francis Ashley Faught, Philadelphia: It is my firm opinion that the renal function test has very little value; it does not differentiate between a temporary congestion of the kidney and chronic kidney disease, and is, therefore, absolutely useless in the study of a condition of this kind which is the borderline between health and disease. Cases of essential arteriohypertension exist and probably have a cause, which is toxic. If such cases do not exist too long as temporary conditions, they are amenable to relief and cure.

1. **Convalescent Human Serum Treatment of Influenzal Pneumonia.**—The observation and treatment by McGuire and Redden of over 400 cases of influenzal pneumonia in the Chelsea Naval Hospital has afforded opportunity to compare various methods of treatment with a fair degree of accuracy. The use of serum from convalescent influenzal pneumonia patients was first tried on two patients with a very severe and extensive bronchopneumonia. The result was very encouraging and led to its further use. Thirty-seven patients have been treated with serum. Thirty are convalescent; six are under treatment; one dead. Of the six under treatment, two are much improved; two have received only one injection of serum; two not improved, one of whom is critically ill. Of the thirty convalescents, eight received treatment on the second day of the pneumonia; fifteen on the third day; four on the fourth day; three on the sixth day. Of the six under treatment, three received serum on the second day; two on the third day, and one on the fourth day. The patient who died received the first serum on the fifth day. Convalescent patients were bled as soon as convalescence was well established, the majority within a week or ten days of a drop to normal temperature. The serum was given as early as the diagnosis of the pneumonia complication could be made, so there has been no doubt about the lung involvement.

The dose of serum has varied from 75 to 125 c.c. intravenously and the interval between doses has varied from eight to sixteen hours. Treatment was continued until there was no doubt about the recovery of the patient. The majority of patients received about 300 c.c. Three received only 100 c.c. and two received from 600 to 700 c.c. It was found that there was a marked difference in the potency of the convalescent serum. At least ten out of seventy serums had no effect on patients. Under these conditions the succeeding doses of serum were from other patients. Results from this serum are usually obtained in the first twenty-four hours after its use. If no results are obtained in this time, the serum from another donor should be used. An attempt was made to judge the potency of the serum by the amount of lung involvement.

Wassermann tests were made on all donors as soon as possible in order not to waste time on bleeding those who showed a positive reaction. Compatibility tests of donors' serum, with recipients' corpuscles, was made as soon as new cases appeared on the ward. Then usually ten to fifteen serums were tested against the corpuscles of each recipient in order to have plenty of available serum for complete treatment. Blood to the amount of about 800 c.c. was taken from each donor, under sterile precautions; 400 c.c. at a time on two successive days. Thus each donor yielded about 300 c.c. of serum. The blood was allowed to clot at room temperature for about an hour, then plate cultures were made, and the containers placed on ice over night. The separated serum was cleared by centrifugalizing at high speed; then bottled, and in most cases given the same day. Tricresol (0.30 per cent.) was used only in serum kept over twenty-four hours. Only four patients had chills after the serum injections. All of these received serum containing tricresol, while three others receiving tricresolized serum gave no such reaction. At no time has a donor been inconvenienced by the withdrawal of the above amount of blood. Experience shows that the most beneficial results will be obtained by giving the proper serum within the first forty-eight hours of the pneumonia complication. The authors are convinced that the serum from convalescent influenza pneumonia patients has a decided influence in shortening the course of the disease and in lowering the mortality.

3. **Open Air Treatment of Influenza.**—Brooks calls attention to the fact that there is apparently great opposition to open air treatment among many of the medical fraternity. Many seem inclined to think that if the windows of a room are open the same object is attained. Many think that the ordinary sun parlor of a hospital is "just as good." The facts are, however, that the patients do not thrive as well in any ordinary hospital, no matter how well it is ventilated, as they do when they are put right out into the open. The objection to the sun parlor is that one gets direct sunlight only during part of the day, whereas the patient who is out in the open gets the direct sunlight all day long. Brooks reports his experience in the treatment of influenza in tents. The efficacy of open air treatment has been proved, Brooks says, and one has only to try it to discover its value. His paper represents the result of study by twelve or fourteen men, who, for a month, practically devoted their entire time to the treatment of influenza and its complications.

5. **Use of Influenza Vaccine in Present Epidemic.**—Three strains of influenza bacilli obtained from cases during the present epidemic have been used by Leary in the manufacture of vaccine. The prophylactic dose has been 0.5 c.c., 1 c.c. and 1.5 c.c. in three doses at twenty-four hour intervals. The therapeutic dosage has been 0.5 c.c. every twelve hours. Leary suggests that it is probable that all of these doses are too small, notably the therapeutic dose. The percentage of complete protection appears to be high, and there is marked amelioration of symptoms in those who become ill, and pneumonias appear in very few cases. The therapeutic use of vaccines was followed by the best results when large doses were exhibited early in the disease. Leary thinks it should be possible to abort a large percentage of the cases, and prevent the development of pneumonia. After pneumonia has developed, large doses of vaccine have produced excellent results.

11. **Fatigue as Contributory Cause of Pneumonia.**—This investigation was made at the Groton School for Boys at Groton, Mass. The kind of fatigue observed as a cause of pneumonia at this school, Cowles says, is an acute fatigue, due to violent exercise like rowing or running in competitive sports and not mere weariness from everyday activities. The observed instances in which acute fatigue was followed by pneumonia were in boys already subject to, or convalescent from, mild respiratory infections and presumably easily tired. That acute fatigue was a contributing cause of pneumonia at Groton, seems more than suggested. Pneumonia was confined to boys given to athletic tasks and sports. Between 4 and 5 per cent. of them had it each year for three years. It came to an end when boys ailing or convalescent were shielded from fatigue. The persons associated with the boys in the school and the high school pupils, near by, limiting themselves to everyday activities, did not have pneumonia. Cowles points out that this investigation suggests the operation of the same contributing cause of pneumonia in army camps and elsewhere, and that the disease may be lessened by similar measures against fatigue in persons out of condition.

24. **Experimental Chemical Pneumonia.**—Wollstein and Meltzer produced lobar pneumonia in dogs by means of intrabronchial insufflation of a broth culture of a highly virulent pneumococcus Type I, invariably leading to a fatal termination. The pneumococcus insufflated was recovered in pure culture from the solid lung area and the blood of the heart. The next step was to apply chloramin-T solution to the inoculated lung. The plan was to introduce 5 c.c. per kilo of body weight of a 1:10,000 solution intrabronchially two hours after the culture was given, and if the animal survived until the next day or longer, to repeat the injection. Six animals with the experimentally induced pneumonia were given the chloramin-T solution; they were controlled by three untreated dogs. One animal received four, another three, and two others two treatments, while two died after the first dose. Instead of a therapeutic action, the effects of the treatment were rather to intensify the pathologic process. Moreover, death resulted, as a rule, more quickly in the treated than in the control animals.

26. **Spirochetal Flora of Normal Female Genitalia.**—The results of examinations of the smegma, films, and washings of the genital mucous membranes of normal adult females demonstrated that the number of spirochetes of the female is much greater than that of the adult male, although the varieties present appear to be identical in both. As in the male smegma, *Treponema calligyrum* is encountered here also as the predominating variety in the majority of specimens, while *T. minutum* is present almost constantly but in fewer numbers. The coarse *Spironema refringens* has been found less frequently here than in male smegma.

28. **Specific Poison in Liver Extracts of Rabbits Inoculated with Typhoid and Prodigiosus Bacilli.**—The experiments described by Parker make it probable that part, at least, of the intoxication produced in rabbits by injections of *B.*

typhosus or *B. prodigiosus* is due to liver poisons of the nature of those dealt with here and which appear to be yielded to the blood by the liver, and then absorbed by the various tissues. Rabbits actively immune to *B. typhosus* or *B. prodigiosus* exhibit a condition of resistance apparently because of having acquired in the process of immunization a tolerance to the liver poison. For it is possible that even if several lethal doses of the bacteria are injected into the immune animal, not more than one lethal dose of the liver poison is produced in a unit of time, an amount which the immune animal can tolerate readily. Whether a similar poison is generated in typhoid in man is a question, Parker says, that cannot now be answered. It seems not impossible that it may play a part in causing the symptoms of toxemia in that disease.

30. **New Thoracic Murmurs Heard with Refractoscope and Partial Stethoscope.**—With these instruments the following facts have been determined by F. D. Parker. The sounds heard through the refractoscope and through the partial stethoscope are different in many respects from those heard in ordinary auscultation. There exist "sound shadows," and of these there are two varieties, respiratory sound shadows and cardiac sound shadows. Heart sounds appear to take on the characteristics of chamber sounds in a degree greater than has been realized; and dilated hearts with poor muscle respond to more harmonics than does muscle with better tonus. The so-called third heart sound, noted by many observers and discussed by both Barie and Thayer, does exist as a true heart sound. It is the sound produced during auricular systole and is heard best at the apex.

There is a cardiac sound which Parker calls the "outflow" sound. The heart is a tube with resonant walls. These walls are set in vibration: (1) while the heart is filling; (2) when the auricle contracts; (3) when the ventricle contracts, thus causing the valves to vibrate; (4) while the ventricle is being emptied; (5) when the semilunar valves close. The flow of blood into the heart is too gentle to cause vibrations sufficient to give rise to audible sound. The second or auricular vibration causes the sound of Barie and Thayer. The third sound is that now termed clinically the first sound. The fourth is Parker's outflow sound. The fifth is the so-called second sound. The outflow sound is heard between the first and second valve sounds of the heart. During this period the outflow sound does not appreciably vary in intensity, but it noticeably rises in pitch. When the ventricle shoots its considerable mass of blood into the great arteries, it is probable that the rushing flood would set the elastic walls in vibration. The outflow sound cannot be a continuation of the so-called first sound, because the intensity of the outflow sound does not perceptibly diminish. In all sounds emanating from the thorax the pleaurae are in a state of vibration. Some sounds produced in the more remote parts of the chest are brought to a focus in the apex of the lungs.

32. **Experimental Hemochromatosis.**—In rabbits destroying transfused blood constantly during a period of many months a pronounced and widespread siderosis ensues, practically identical with that characterizing human hemochromatosis. The findings do not indicate the ultimate cause of this disease, but they throw light on its various features and its course, and suggest a means for its diagnosis.

33. **Hemosiderin Granules in Urine as Aid in Diagnosis of Diseases Causing Siderosis of Kidney.**—In diseases which bring about a siderosis of the kidney, there are ordinarily present in the urinary sediment cells containing granules of hemosiderin, and often many free granules as well. The finding has proved useful in the diagnosis of hemochromatosis and Rous suggests that it will probably be of service in the recognition of pernicious anemia, and possibly some other diseases. The fact should be emphasized that urinary siderosis is the indication of a renal condition, not of a disease.

38. **Gold Salts in Treatment of Experimental Tuberculosis.**—From DeWitt's experiments the conclusion is drawn that the treatment of experimental tuberculosis in guinea-pigs with gold salts is not efficacious. No attempt has been made to use these salts in human patients. The tendency to hemorrhage and hyperemia in the gold treated animals and the marked shortening of life on account of the treatment suggest that the treatment of human tuberculous patients with gold is not without danger. Furthermore, the chemical analyses of the organs demonstrate that there is no specific affinity of gold for tuberculous tissues and that the gold in the tissues is probably fixed in the tissue cells in such a form that it cannot inhibit the growth of the tubercle bacillus nor the development of the tubercle even when its concentration in the tissues is much more than sufficient to cause complete inhibition in the test tubes.

40. **Leukocytes and Marrow in Pneumonia.**—Samuels and Lambert made their observations on seventeen cases of acute lobar pneumonia which came to necropsy. Only adults were included in the series, since in the earlier periods of life the bone marrow in the long bones is normally so active that degrees of hyperplasia cannot be easily recognized. A close parallelism in the leukocyte count and the degree of hyperplasia of the marrow was found in less than half of these cases. A few showed relatively inactive or aplastic marrows, with a leukocyte count well above normal. On the other hand, in several cases leukocyte count was persistently low during life, but a markedly hyperplastic marrow was found at necropsy. To explain an aplastic femur marrow associated with a leukocytosis during life there may exist either a hyperplasia of the marrow of the flat bones only—a very improbable condition—or a formation of leukocytes outside the marrow, most probably in the spleen. The presence of large numbers of cells of the myeloid series in the splenic pulp would favor the latter explanation. The cases of marked hyperplasia of the marrow with low leukocyte count are not easily interpreted. The authors could not find evidence in these cases of such rapid spread of the lesion as would account for a low leukocyte count through the draining of these cells out of the circulation.

41. **Case of Spirillosis.**—The occurrence, in a young Italian, of a recurrent fever characterized by acute exacerbations, accompanied by severe secondary anemia, general lymph node involvement, splenomegaly and varying lung symptoms, and the isolation from the blood both during life and at necropsy of a motile curved organism are the salient features of the case cited by Hartman and Lacy. The resemblance to typhoid during the earlier course of the disease was striking save that all of the laboratory tests were consistenly negative. The diagnosis of a generalized tuberculosis was not corroborated. The most unusual feature was the sudden enlargement of the lymph nodes with subsidence within a few days to a more nearly normal size. A study of the sections suggests that enlargement was due to a severe inflammation of the intranodal sinuses which healed by granulomatous changes leading to extensive connective tissue development. The progressive secondary anemia was extreme, and there were no evidences of blood regeneration found either in the blood examinations or in the sections of the marrow. The marrow was red but the sections showed the color to be due to necrosis and hemorrhage and not to hyperplasia. The hemosiderin in the liver and spleen as well as

the extreme phagocytosis of red cells in the latter showed that the anemia was due not only to the failure in production of red cells, but also to actual blood destruction in the tissues. The splenomegaly was probably secondary to the anemia. A few small foci of nodular connective tissue, slight edema and the pleural hemorrhages were all that were present at necropsy to explain the lung symptoms. Anatomic changes associated with the diarrhea and general toxic condition were seen in the stomach ulcers, the membrane in the colon and in the necroses of the liver. The main point of interest is, of course, the isolation both before and after death of an actively motile, spirally curved organism from the blood. The spirillum grew equally well aerobically and anaerobically.

42. **Liberation of Antibodies by Foreign Protein.**—In rabbits sensitized with streptococci Herrman found that a definite liberation of specific opsonins and agglutinins follows the injection of foreign protein. A similar rise in specific opsonins also occurs in rabbits sensitized with meningococci. Foreign protein injections have no effect on antibodies in typhoid immune rabbits. In suitable rabbits, which do not readily produce lysins against sheep corpuscles, the injection of foreign protein within ten days after the injection of antigen is followed by a marked liberation of specific lysins. A variety of foreign proteins can be used. Human serum, typhoid vaccine, human ascitic fluid, and guinea-pig serum proved equally efficacious.

43. **Meningococcus in the Blood.**—During the epidemic at Camp Beauregard in February, 1918, twenty-seven blood cultures done by Maxcy on patients suspected of being cases of abortive meningococcus infection were negative. A case of meningococcus infection is reported in which the blood stream invasion was transient and the organism quickly localized in the meninges where it yielded to the intraspinal injection of serum. A case of meningococcus septicemia with transient meningeal involvement is reported with recovery only after the injection of large amounts of antimeningococcus serum intravenously.

44. **Acute Respiratory Diseases and Empyema.**—In a group of 115 consecutive cases of pneumonia and empyema occurring at Camp Custer a definite history of an acute antecedent bronchitis, pharyngitis or tonsillitis was obtained in over 80 per cent. of the cases. In the majority of cases of empyema, a hemolytic streptococcus was the causative organism. During the period of prevalence of emypema, streptococci were demonstrable in the majority of the throats of healthy soldiers (including fresh recruits) as well as of patients entering the hospital with respiratory infections. The mortality was highest (61.5 per cent.) in the cases of empyema following measles, and lowest (22.7 per cent.) in the cases in which empyema was the primary condition. In empyema complicating pneumonia, the mortality was 38.2 per cent.; the mortality of all cases of empyema was 40.5 per cent. At necropsy the outstanding features have been the finding of widespread lesions with a tendency to involve serous membranes, the occurrence of a severe bronchitis in the majority of cases, and a type of bronchopneumonia so distributed as often to resemble closely a lobar process.

The relative incidence of empyema complicating pneumonia was high, one month 50 per cent. of pneumonia cases developing empyema. Of 830 cases of measles (including rubella), 4.4 per cent. developed pneumonia or empyema; of this group, empyema was the primary condition clinically in 70 per cent. of the cases.

63. **Case of Aspirin Habit.**—Macht cites the case of a man who had a chronic periostitis and osteitis of one tibia, who about two and a half years previously found that a tablet of acetylsalicylic acid (aspirin), 5 grains, gave him distinct relief, and therefore he continued to take the drug for the relief of his symptoms. At the beginning one or two 5-grain tablets were sufficient to keep him comfortable the whole day, but very soon habituation was noted and the patient had to increase the dose. For the past two years he has been taking from five to twelve tablets of the drug daily; in other words, from 25 to 60 grains of the drug have been consumed by the patient every day for nearly two years. In spite of the enormous quantity of the drug consumed, very few toxic symptoms have been noted by the patient himself or found on physical examination. The only features of a slightly abnormal character found were obstinate constipation, slight digestive disturbances, and a rather low blood pressure.

76 *Simplified Method *of Aspirating Gastric* Contents in *Hypersensitive* Patients. C. D. Aaron, Detroit.—p. 440.

76. **Simplified Method of Aspirating Gastric Contents in Hypersensitive Patients.**—Aaron believes that it is possible to strip this procedure of its terrors and inconveniences by not allowing the tube to enter the stomach at all, and yet obtaining a quantity of gastric contents sufficient for chemical and microscopic analysis. In devising this process, he has been guided by a consideration of the anatomic fact that the lower third of the esophagus is normally distended, forming a continuous open lumen. As soon as the stomach tube reaches that part, the cardia, following the law of contrary innervation, becames relaxed, and as a result the gagging and retching of the patient induces a regurgitation of some of the gastric contents into the esophagus, where

the fenestrated end of the stomach tube is ready to receive it, and whence it is promptly aspirated by the atmospheric vacuum action of the terminal rubber bulb. Thus it is quite unnecessary for the tube to enter the stomach, and the greater the gagging and retching of the patient the easier it is to obtain a sample of the gastric contents. This arrangement also overcomes what has long been considered another difficulty, namely, an abnormally low position of the stomach, where the tube cannot reach the surface of the gastric contents. The reflex effect of the irritation of introducing the tube beyond the tracheal bifurcation causes the contents of the stomach, however low, to regurgitate into the esophagus through the relaxed cardia and thus obligingly meet the receptive stomach tube half way.

77. **Cerebral Glioma.**—Sands cites the case of a man suffering from hemiplegia with loss of sphincteric control for about one year prior to his death. He showed general arteriosclerosis, blood pressure, 170 systolic, sluggishly reacting pupils; positive globulin and twelve cells, but negative Wassermann, in the spinal fluid. Mentally, he was somewhat incoherent and rambling; he exhibited patchy amnesia with preservation of personality. Postmortem examination showed a glioma in the right parietal region, cerebral and visceral arteriosclerosis, and bronchopneumonia.

104. **Flagellated and Ciliated Protozoa.**—In the past the attention of parasitologists and physicians has been focused largely on the effects of the parasite on its host—a most natural point of view. But in reviewing the subject, especially in the light of recent evidence, Haughwout says, it is hard to escape the impression that the host, on occasion, may transform an apparently harmless parasite into one that is pathogenic or even lethal to its host. This is entirely apart from conditions of lowered vitality and resistance, which proverbially favor the development of infections of all kinds. He suggests that the term "harmless commensal" has been very much overworked. The case of the intestinal nematode *Ascaris lumbricoides* is in point, and apparently the day is not far distant when the terms "harmless commensal" and "symbiont" will be used in the literature with much greater caution than has been shown in the past. It has long been Haughwout's belief that time would show that all animal parasites that have been regarded as commensals and symbionts in the alimentary tract, if not actully giving rise to lesions, would yet be shown to affect unfavorably the physiologic balance of the host in some way. This paper deals with that thought.

105. **Serum Treatment of Bacillary Dysentery.**—According to Lantin the use of specific treatment seems to be an effective means of checking the progress of the disease in cases of true bacillary dysentery. Of twenty patients whom he has so treated only one patient died. Different methods of administering the serum, namely, intramuscularly, intravenously and by rectum (serum enema), have been employed. Out of seventeen cases in which cultures were made from the feces, six were negative. Of the eleven cases that were found to be positive, two were of the Shiga and one of the Flexner type. Of these twenty cases, five patients were treated medicinally, combined with intramuscular injection of serum, with one death; six patients intramuscularly with no deaths; three patients treated both with intramuscular injections and antidysenteric serum by rectum with no mortality; three patients treated solely with serum by rectum with no deaths; and finally, three patients treated intravenously, with no deaths.

The serum by rectum was given in the following way: The patient was put in the knee chest position. The injection of the serum was preceded by a cleansing enema of 1.5 per cent. solution of sodium bicarbonate; this was followed by another enema of starch solution with a few drops of tincture of opium (60 c.c. with 10 drops of tincture of opium) to diminish the irritability of the intestine; a half hour later the serum was given by rectum. The amount of serum used was from 30 to 50 c.c. daily, depending on the severity of the case, although the serum can frequently be given without any danger and in larger doses. The intramuscular administration of serum was done with the usual aseptic precautions. Twenty c.c. of the serum were given twice a day, usually injected into the buttock. Larger doses may be given, depending, of course, on the severity of the case. Intravenous injection was done by the closed method, and under rigid asepsis into the median basilic vein. To avoid anaphylactic symptoms, 1 c.c. of the serum may be injected intravenously about six hours before the full dose is given. Lantin's dosage was 10 c.c. every other day.

1. **Paratyphoid in Children.**—Stolkind and Lorey state that a study of the results of postmortem examinations of paratyphoid cases in children and adults, including those reported in the literature and their own cases, shows that the morbid changes have been observed resembling (1) typhoid; (2) acute enteritis, acute gastro-intestinal catarrh, or acute gastritis, etc.; (3) dysentery; (4) those of a transitional form, that is, inflammation of the intestinal lymphatic apparatus (swollen follicles and Peyer's patches, etc.); (5) septicemia. In some cases no changes in the gastro-intestinal canal were found. Stolkind and Lorey have not been able to find a single recorded case of proved paratyphoid in a child in which the lesions, at the necropsy, resembled those typical of typhoid. They also record a case of intra-uterine infection with *B. paratyphosus* B in the blood of a newborn child. The blood culture and positive agglutination showed *B. paratyphosus* B. The mother had had acute gastro-enteritis with fever some time before. Cases are also recorded of the I. typhoid form of paratyphoid; II. gastro-intestinal form of paratyphoid; III. the choleraic form, and IV. influenzal or respiratory form. The clinical history of the disease is described in detail.

In the treatment of a case of paratyphoid the authors point out that the nursing, general hygiene, diet, and in severe cases drugs are of great importance. Generally the authors give liquid food. In mild cases of the typhoid and respiratory forms they allow the older children biscuits, cooked minced meat, etc.. Alcohol should not be given in any case. If stimulants are needed, use tea, coffee, caffein, digitalis, camphorated oil, etc. In many cases of profuse diarrhea, collapse, etc., repeated subcutaneous injections of normal salt solution (one-half to 1½ liters) were of value. For abdominal distension proper diet is required. Turpentine proved absolutely useless in all cases. For toxic meteorism as well as for bacteriotoxic paralysis of the vessels (with frequent filiform and irregular pulse, dyspnea, general weakness, perspiration, pale or cyanotic skin, and sometimes collapse with fall of the temperature), subcutaneous injections of epinephrin with normal salt solution (six to ten times in twenty-four hours), caffein and camphorated oil were sometimes of use. Fever should be treated by hydrotherapy (baths not below 85). Intestinal antiseptics have no value. Vaccines may be employed in severe cases.

19. **Serologic Investigation of Vincent's Angina.**—In only two cases out of a total of fifty-five cases of Vincent's angina which were examined by the Wassermann test was the reaction positive, the remaining fifty-three cases being negative. The positive character of the reaction in these two cases was not due to the fusospirillary infection of Vincent. In both cases the condition was one of Vincent's angina in a subject of latent syphilis. As a result of this investigation and of a careful and critical consideration of cases recorded in the literature, Taylor and McKinstry have come to the conclusion that the prevailing belief in the occurrence of a positive Wassermann reaction in Vincent's angina has no foundation in fact, and that the two conditions can be differentiated with absolute certainty by the application of bacteriologic and serologic methods; and that when the complement fixation test of Wassermann is positive in cases of Vincent's angina, then a double infection exists, either as a coincident syphilitic and Vincent's infection, or as the occurrence of Vincent's angina in the subject of latent syphilis.

23. **Gunshot Wounds of Joints.**—Gunshot wounds involving joints form something like 4 per cent. of the total number of wounds met with in the present war. Campbell's paper is founded on an experience of over 800 cases and on operative and postoperative treatment carried out in casualty clearing stations and general hospitals. Campbell says that absolute rest and fixation are the essential principles underlying the successful treatment of all joint wounds in their early stages, and their value cannot be overestimated. The best method for securing them, whether for transport or treatment, is by fixed axial extension of the limb in one of Thomas' or Jones' splints, the limbs being supported in it by bands of perforated zinc, the ends of which are turned round the lateral bars; finally, the limb is well padded, covered with Gooch's splinting, and secured in the splint by a firm bandage. To insure an absence of movement during dressings it is essential for as few as possible of the metal supports to be removed, and then only with the greatest care. No movement, however slight, should be permitted. The use of strips of flannel or cotton bandage to support the limb is strongly condemned by Campbell. They are not rigid, and so permit of an appreciable amount of movement in bed and during transport—sufficient to vitiate the result in many of the more serious cases.

The need for rest and fixation by no means begins in the casualty clearing stations; it is essential for them to be secured at the time the patient is wounded or at the next earliest moment possible. Plaster of Paris is sometimes used instead of splints to secure fixation—in late stages of convalescence it is useful to allow of the patient's getting about. But in early septic cases its use is attended with many disadvantages. Chief of all is the impossibility of preventing the plaster from becoming soiled with the septic discharge from the wound; this then forms a center from which the wound is constantly reinfected. Another important disadvantage is that it does not allow of access to the adjacent parts of the limb, thereby preventing all possibility of massage and obscuring any changes in the neighborhood of the joint.

Asepsis should be secured at the time of operation. Dressings should be changed as infrequently as possible for two reasons, (1) the risk of movement, and (2) the risk of fresh infection from without. To insure a good range of movement it is advisable for massage and movement to be begun as early as possible in cases that have run an aseptic course, that is, about the tenth lesion. Cases that have been septic even to only a moderate degree should have been free from all clinical signs of infection for at least three weeks or even longer, according to the degree of sepsis, before movement is resorted to. The appearance of effusion in the joint or of general or local reaction after movement is an indication for a pause in its application.

The resumption of movement in joints where foreign bodies are retained is liable to be attended by trouble that may quite easily cost the patient his limb. Unless the foreign body is removed by operation, movement is best postponed for at least several months. The application of a tourniquet to the limb prior to operation is essential if a uniformly high standard of results is to be obtained. Washing out of the joint cavity, as a routine measure at a primary operation where the joint is laid open, appears useful.

Every attempt should be made when dealing with early wounds to prevent blood accumulations by obliterating all "dead space" and yet allow of drainage of any exudate that may take place. If primary suture is performed, this may be accomplished by careful hemostasis, followed by the application of a very firm bandage. Should, however, the wound be unsuitable for primary suture or, with suture, still show a dead space, these objects can be gained by using as a pack gauze soaked in sterilized liquid paraffin; this is carefully and firmly pushed into every recess and the limb firmly bandaged. The pack exerts pressure, and so helps in hemostasis, and the paraffin hinders coagulation of blood and serum, and so allows of their drainage along the gauze into the more superficial parts of the dressing. Such a pack may be left in situ for two to four days or longer, the superficial parts of the dressing being changed on the first or second day only if the "dressing has come through." When the pack is removed it may be replaced by paraffinized or dry gauze as required, unless the wound can be entirely closed. The cases in which this treatment yields excellent results are those showing large loss of bone substance involving articular cartilage, and in which the synovial cavity cannot be closed for anatomic reasons.

Unless the wound has been excised en masse, Campbell says, the use of fat grafts to obliterate dead space would seem to be not unattended by risk. Where, however, asepsis can be reasonably guaranteed they yield excellent results. Should any gap be left in an articular surface, one way of obliterating it that yields useful results is to fill it up with a 2 per cent. paste of dichloramin-T in neutral sodium oleate or neutral sodium stearate before closing the joint. A mass of bismuth iodoform petrolatum paste should not be used owing to the risk of bismuth poisoning arising shortly afterward or from the danger of its acting as a foreign body and being extruded later on. Secondary operations in a base hospital are not infrequently required. It is essential to carry them out without removing the splint. To attempt otherwise courts disaster from a recrudescence of septic arthritis with its attendant consequences.

Aspiration is useful in doubtfully infected cases for the purpose of making bacteriologic and cytologic examinations of the joint fluid, but if carelessly performed the damage done to the articular cartilage and synovial lining may immeasurably outweigh the advantages gained. It is advisable to use it as rarely as possible in those cases that are but mildly septic; indeed, here it is scarcely necessary, since the ordinary clinical signs yield information of more practical value for treatment. It is necessary, however, when the intra-articular tension becomes high, otherwise the infection may burst outside the synovial cavity and perhaps track widely along the fascial planes. Exploration and washing out of the joint cavity followed by suture appears to have but a limited application. Such cases as seem suitable for the treatment almost invariably settle down if carefully immobilized in the extended position and left severely alone, aided, perhaps, by aspiration; in those cases in which it is used further operative procedures have nearly always to be resorted to. Should this procedure be adopted, free exit for the fluid should be permitted for fear lest any recesses in the joint cavity that are already locked off by adhesions should be opened up and have sepsis driven into them. All flakes of blood clot, fibrin, and pus should be sought out and removed; finally, the limb is bandaged tightly to prevent exudation and allow of the rapid formation of adhesions.

Morisons' bismuth iodoform petrolatum paste seems to have two valuable fields of use: (*a*) In cases in which a portion of the bone inside the joint has been chiseled away it is advisable to smear a small quantity over the freshly cut surface prior to closing the joint. (*b*) In cases, for instance, the knee, where, after operation, a large gap that cannot be repaired is left in the joint coverings, accompanied by a more or less extensive loss of subjacent bone involving the articular surface, bismuth iodoform petrolatum paste may be smeared over the entire wound surface after excision and the wound closed so far as possible in layers either at once or by delayed suture, after having carefully obliterated dead space with a paraffinized gauze pack. In the treatment of septic arthritis bismuth iodoform petrolatum paste has been largely advocated and not infrequently adopted. Bismuth iodoform petrolatum paste used in this way inside a joint has a serious drawback; it may be ejected later on as a foreign body and so cause considerable trouble on resumption of movement.

In early cases, after efficient excision of the wound, the Carrel-Dakin method need be adopted only. There is no doubt that simple primary suture or delayed primary suture after using bismuth iodoform petrolatum paste yields the better results. On the other hand, when sepsis develops, in the large majority of cases the Carrel-Dakin method yields the better results. Excision of the joint can be used for either early or late cases, and may be either partial or complete.

Amputation is reserved for: (*a*) Patients who are too ill to allow of conservative measures being adopted. (*b*) Cases in which the comminution of bone is so extensive as to preclude the possibility of successful end-result. (*c*) Wounds accompanied by severe lesions of the main nerves and muscles. (*d*) Wounds in the lower limb accompanied by serious damage to the main vessel and in which there is considerable risk of gangrene. (*e*) Septic cases, in which an extensive osteomyelitis of a large bone, for instance, femur or tibia, is also present.

25. **Prophylactic Vaccinations Against Catarrhal Affections of Respiratory Tract.**—The vaccine used in this work was prepared in two different strengths, the weaker initial dose being followed ten days later by the second stronger dose; in each instance the volume of vaccine administered amounted to 0.5 c.c. This vaccine was prepared from organisms contained in the secretions of purulent bronchitis and in the sputums of other catarrhal cases among the troops in England. It contained:

Organism	Organisms per 0.5 c.c. First Dose	Second Dose
Pneumococcus	50	100 million
Streptococcus	10	50 million
B. influenzae	10	30 million
Staphylococcus aureus	200	500 million
M. catarrhalis	25	75 million
B. pneumoniae	50	100 million
B. septus	50	100 million

This vaccine was designed to produce an artificial immunity, not only against the first three virulent organisms, which are frequently found present in fatal purulent bronchitis, but also to immunize against the other organisms most frequently found in catarrhal sputums and nasal discharges. There may be no reaction, but in such cases the immunity conferred may be as efficient as in those who react. There may be slight reaction. This is the most likely sequela, and will probably occur during the twenty-four hours following inoculation and, apart from a possible tenderness at site of injection, may produce a mild general malaise, tiredness, stiffness, and slight headache. In cases with existing catarrhal discharges these may be temporarily aggravated. There may be severe reaction. This is not expected except in a small percentage of cases. There will develop during the following twenty-four hours an aggravated condition of the above symptoms, and also probably a rise of temperature and pulse rate. In these cases at least fourteen days should be allowed to elapse before the second dose is given. Severe reactions may possibly occur if the occasion of inoculation happens to coincide with the onset of measles, etc. The immunity conferred will probably not last longer than twelve months, and it should not be forgotten that there is always a certain percentage of persons in whom it appears impossible to produce any immunity.

Results: (*a*) 2,081 men inoculated with the initial dose. No reaction, 2,033, 97.7 per cent.; slight reaction, 42, 2.0 per cent.; severe reaction, 6, 0.3 per cent.; (*b*) 1,627 men inoculated ten days later with the second dose. No reaction, 1,607, 98.8 per cent.; slight reaction, 3, 0.7 per cent.; severe reaction, 7, 0.4 per cent. Slight reaction: headache in twenty-four cases; temperature from 99 to 101 in fourteen; sore throat in five; neck stiffness, nausea and fainting in five. Severe reaction: above symptoms more marked and accompanied by temperatures between 101 and 104. In spite of their being so small evidence of immediate reactions there was an increased susceptibility to the prevalent catarrhs of the area. These data show that the extensive use of catarrhal vaccine will not incapacitate troops in training to any appreciable extent. In order to determine whether these inoculated men had gained any appreciable immunity to respiratory catarrhal complaints, the first 1,000 men inoculated, and another selected 1,000 men none of whom had been inoculated with this or any other catarrhal vaccine were watched. It was found that the incidence of the influenza epidemic was appreciably less among the inoculated men than that affecting the average 1,000 of the uninoculated (2 per 1,000, as against 28.4 per average 1,000), a result which amply justifies the prophylactic use of M. C. V. The experimental work on which prophylactic, and still more therapeutic, vaccination was originally based showed clearly that, quite apart from the immediate local and general reactions, there supervened a period of lowered resistance or increased susceptibility toward infection by micro-organisms of the same species as those constituting the antigen, and that this so-called "negative phase" varied in extent from a few hours to two or three weeks, in accordance with the size of the dose of antigen, the general physical condition of the inoculated subject, and other factors. Fifteen admissions were reported between the administration of the first and second doses of M. C. V., and during the ten days following the injection of the second—much larger—dose of vaccine no less than eighty-two patients were admitted. Of course, most of these were quite trivial, and in the ordinary course of events, and among uninoculated men, would never have been admitted, but, nevertheless, even when heavily discounted, these figures emphasize the reality of the "negative phase," and prompt the suggestion that the initial dose might, with advantage, have been somewhat larger, or preferably that the interval between the two inoculations should have been a few days longer.

32 *Trephining the Newly Born. A. Brindeau.—p. 103.

33 *Puerperal Infection with Diphtheria Bacilli. P. Balard.—p. 135.

31. **Mishaps from Radiotherapy.**—Recasens and Conill discuss the action of the roentgen and radium rays on the blood, the blood-producing organs, digestive, urinary and nervous systems, the sensory and the endocrine apparatus, on the pregnant, and on toxemia, metastases and dermatitis. They warn of the danger of gangrene when the skin is incised in a region that has been exposed to the roentgen ray. In one of their cases the apparently completely healed laparotomy wound sloughed open three weeks later and it did not heal again for five months. Since then they refrain on principle from roentgen exposure of the exact median zone of the abdomen for fear that a laparotomy might be necessary at some time. The vagina seems to be less susceptible than the skin. There is always a drop in the numbers of leukocytes after roentgen exposures, and they do not return to and somewhat surpass their former figure until after about two weeks. This leukopeny implies lessened powers of resistance, while the leukocytes that have been destroyed release leukotoxins into the blood stream. Toxins are also poured into the circulation when degenerated myomas and cancers are exposed to the rays unless they are well opened and drained. In much debilitated patients this toxemia may prove disastrous.

They warn further that as the primal effect of small doses of the roentgen and radium rays is stimulating, it is important to beware of beginning with small doses which might whip up the malignant disease. They are inclined to accept as an important factor in malignant disease a reduction in the numbers of leukocytes and of connective tissue cells; this suggested the advantage of combining local action of radium with means to stimulate leukocyte action. This they accomplished with diathermy applied to the spleen, and have had surprisingly favorable results with this in cases with such debility that a cure seemed hopeless. The removal of a cancer does not signify a cure so long as the numbers of leukocytes and of connective tissue cells keep low. Sometimes moderate radiotherapy may do great good by increasing these figures although, directly, little influence on the cancer itself is apparent. On the other hand, extremely high doses injure the leukocytes and the connective tissue cells, so that after a phase of transient benefit the cancer progresses more than if nothing had been done.

Rectovaginal fistulas originating from a cancer are permanent, but a fistula of the kind developing from dystrophy under radium treatment of a cancer may heal spontaneously.

They have had this occur in two cases. The bladder tolerates better than the rectum the action of the radium. Good filtering and prudent doses ward off fistulas; they use a brass filter, 1.5 mm. thick, covered with a rubber cot to absorb the secondary rays when the radium is to be used in contact with the sound wall of the vagina. They begin with 70 mg. for twenty-four hours, repeated with 40 mg. with intervals of eight or ten days, up to six or seven applications. Then after a two months' rest the initial dose is repeated. Four months later, if there is still any hard lump, one more application of 60 mg. is made for twenty-four hours. This dosage does not have the inconveniences of strong doses. Too big doses, besides fistulas into the rectum or bladder, are liable to induce necrotic processes, and fuse together the uterus, ovaries, tubes and bladder by an aseptic suppuration with multiple adhesions. Rapid metastasis, occurring with proper dosage, must be regarded as a casual coincidence. They advocate removal of most of the vegetating masses preliminary to the radium exposures to keep down to the minimum the toxemia from absorption. This toxemic reaction grows much less with succeeding exposures.

32. **Trephining the Newly Born.**—Brindeau has done this in four cases; twice for fracture with removal of a sequester, and complete recovery. In the other cases with meningeal hemorrhage of several days' standing, the trephining came too late or necropsy showed already irreparable lesions. The procedure is not so serious as might be supposed; a very narrow opening is enough to correct a depression of the bone. For hemorrhage, he found the operation simple and the drainage perfect, cutting an inverted U shaped flap, the apex just below the parietal protuberance. The groove cut in the bone parallels the radii starting in the parietal protuberance. The dura is incised in this groove. In fifteen hemorrhage cases on record, four of the children were saved. The conditions were exceptionally grave in all. The literature on the subject is reviewed, and four diagrams show the course of the blood vessels to be avoided, especially the anterior region of the dura mater close to the frontoparietal suture. The middle meningeal artery in the newborn slants upward and forward, instead of backward as in adults. There can be no question as to the necessity for immediate correction of any depression in the skull. The depression may occur spontaneously, the contraction of the uterus forcing the head of the fetus against the promontory.

33. **Puerperal Infection Due to Diphtheria Bacilli.**—Balard reports a small epidemic of eight cases of diphtheritic inflammation and false membranes in the vulva in the Bordeaux maternity. The women's infants were given them only to nurse, and none contracted diphtheria, and no throat cases developed from them; and the infectious process was mild. The epidemic was traced to one parturient with a mild sore throat, the true nature of which was not suspected at the time. There was no fever in any case, and antitoxin was not injected. The false membranes did not yield to any of the usual local measures, but they yielded to one or two local applications of diphtheria antitoxin. In two other cases, at the same time, false membranes developed in the vulva thicker, more confluent and tenacious, and not affected by antitoxin. No diphtheria bacilli were found in them, and they subsided under repeated cauterization with tincture of iodin. The ten women were in the common ward, but were tended by a separate nurse. In the fifty-one cases of vulvovaginal diphtheria which he has found on record, only 6 per cent. of the infants contracted diphtheria, and none in the milder cases. By the time the diphtheria is recognized in the mother, the child must have been contaminated, but newborn infants are quite resistant to most infections. In the cases in which an injection of antitoxin was given the infant, its harmlessness was corroborated.

38 *Epidemic of Jaundice in Roumania. J. Cantacuzène.—p. 261.

34. **Hemorrhagic Spirochete Bronchial and Pulmonary Infection.**—Barbary reports two cases which deceptively simulated pulmonary tuberculosis. The sputum was blood stained and extremely fetid, and the microscope revealed the presence of spirochetes. The acute form subsides in a few days and the chronic form does not affect the general health much, and usually yields to arsphenamin. The disease seems to have been brought to France by troops from Indo-China. It is contagious, and requires isolation of the patient and disinfection of the sputum. Differentiation by microscopic examination of the sputum is particularly important as otherwise the cases are labeled tuberculosis.

35. **Prosthesis for Popliteal Paralysis.**—The light but strong spring device illustrated holds the foot in the axis of the leg, and flexion and extension proceed normally on the contact of the heel with the ground. It is worn inside the ordinary shoe and trouser leg.

36. **Free Grafts.**—Imbert has never seen unpedunculated grafts of any tissue (except skin) grow in size, but they often become adherent, and newly formed vessels may grow into the interstices, but this does not indicate actual vitality. Only the microscopic determination of living cells, with stainable nuclei, testifies to the persisting vitality of the graft. Even at the best, this vitality is of a low degree, and bone grafts, in his experience, all tended to disintegrate and finally disappeared in the course of a few months.

38. **Epidemic Jaundice in Roumania.**—An extensive epidemic is described among troops and civilians which presented the characteristics of spirochete jaundice but no spirochetes were found at any time, and bacteria resembling the paratyphoid B bacilli seemed to be the causal agent. There were no deaths except that pregnant women invariably succumbed. Fatty degeneration of the liver and lesions in the suprarenals were the chief findings. Cantacuzène suggests that the paratyphoid B bacilli, in adapting themselves to the organism after antityphoid vaccination, may develop into an autonomous jaundice-inducing race which, in its turn, may generate an aberrant clinical type.

49 Committee Report on Hospital Medical Courses for Foreign Students. P. Sainton.—p. 739.

39. **Elimination of Quinin.**—The research done on dogs showed that quinin injected subcutaneously or by the vein diffuses through the organism. The blood soon gets rid of it, and it is eliminated by the kidneys and digestive tract. Part is fastened temporarily by the brain, spleen and liver, but later this is taken up by the blood and eliminated with the rest.

40. **Glycosuria After Gastro-Enterostomy.**—Le Noir found alimentary glycosuria in a certain proportion of persons who had had gastro-enterostomy done for ulcer at the pylorus. It seems to testify to some insufficiency of the pancreas and duodenum.

41. **Duodenal Dyspepsia.**—Gaultier reports cases in which chemical tests of the duodenum functioning revealed marked reduction in the amylolytic, trypsic and steapsic power while the stools showed profuse steatorrhea and deficient bile production. A gastro-enterostomy for ulcer at the pylorus had been done not long before; and the laboratory findings confirmed the clinical impression of duodenal dyspepsia with involvement of the pancreas or of the biliary apparatus or both. The clinical picture included abnormally large or loss of appetite, pains around and above the umbilicus, some-

times most prominent in the liver region, sometimes over the pancreas. With the former they spread to the right shoulder, with the latter to the lumbar region. They came on two or three hours after eating, a sensation of oppression or violent colics with passage of large amounts of gases. Nausea was frequent but vomiting was rare; diarrhea may alternate with constipation. Tympanites two or three hours after eating is a prominent symptom, and deep palpation may reveal tenderness in the duodenal zone. There is a tendency to a muddy complexion, malaise, somnolence, muscular atrophy and weakness, possibly also alimentary glycosuria, and the urea content is reduced as also the proportions between the total sulphur and the incompletely oxidized sulphur. We thus have it in our power now to detect duodenal dyspepsia with a precision hitherto unknown, and thus apply suitable treatment.

42. **Technic for Study of Duodenal Functioning.**—Gaultier uses Fouchet's sensitive test for bile pigments, and pancreatin for testing the pancreatic power. He describes the technic, believing that it has a future, being more exact than Einhorn's method.

43. **Addison's Disease.**—The typical case reported was distinguished by the lesions of the solar plexus and the fact that the suprarenals were free from tuberculosis.

44. **Bacteriotherapy Plus Serotherapy in Meningitis.**—Florand and Fiessinger report a case in which serotherapy for two strains of meningococci failed to benefit as a third strain was involved. An iodized autogenous vaccine was then used, and prompt recovery followed as also in two other cases described, in which the vaccine and serotherapy were used together. In the discussion that followed, Netter related that intramuscular injections often prove useful to supplement the intraspinal in case of meningococcus septicemia. He has also had encouraging results with vaccine therapy in cases rebellious to serotherapy.

52 Occult Spina Bifida in Adult. Babonneix and Debeyre.—p. 158.
53 Tardy Fulminating Gas Gangrene. L. Courty.—p. 161.

50. **Hemoptysis in Tuberculosis.**—Dumarest reviews the different factors in hemoptysis, ulceration, congestion, high blood pressure and stagnation, emphasizing the different measures required to combat each. The only measures to control hemoptysis are the mechanical, and among these temporary artificial pneumothorax should be included. This insures direct compression and is especially valuable with hemorrhage from an ulceration. The other types of hemoptysis, from congestion, high blood pressure and hypostasis, are comparatively harmless and stop of themselves in the immense majority of cases, or this can be hastened by repose and ipecac, or amyl nitrite to reduce cardiovascular functioning in the cases with congestion, the *type fluxionnaire*. In the cases for which high blood pressure is responsible, dieting, venesection and moderate exercise are indicated. In the hypostatic and dyscrasic type of hemoptysis, tonics to stimulate the cardiovascular system are called for, keeping erect and exercising. As a general thing, aside from emetics, drugs are of dubious efficacy. Unless applied strictly according to the exact indications, they may do more harm than good. In conclusion, Dumarest remarks that in many cases the chief danger from the loss of blood is the risk of retention and infection. Accidents of this kind may be effectually combated by continuous inhalation of oxygen in treatment, or in prophylaxis in all cases of brief hemoptysis.

51. **Contractures After War Wounds.**—Chavigny refers to the hands twisted back on the wrists and other forms of contracture rendering the limb useless after a war wound, which yet did not involve the region directly. He was astonished to find in palpating these cases that the muscles, instead of being contracted, were completely relaxed. But they are in a condition of imminent contracture, and at the slightest attempt to straighten the limb, the muscles tighten and become like iron to retain the contracture. It subsides anew as soon as the attempts at extension are abandoned. The normal interplay of the muscles has been arrested. This special type of imminent defensive contraction differs entirely from the contracture from a wound of the spinal cord or brain. He says it might be called a *contraction de contradiction*. It seems to be exclusively psychic, which explains the cures realized by Boisseau and D'Oelsnitz, recently mentioned in The Journal, Feb. 23, 1918, p. 576.

Revue Médicale de la Suisse Romande, Geneva

54 *General Physiology of Sense of Gyration. L. Bard.—p. 293.
55 *Prophylaxis of Goiter. C. Roux.—p. 317.
56 *Extension Pincers. F. Forel.—p. 321.
57 *Diverticulitis of the Sigmoid. H. C. Krafft.—p. 325.

54. **Sense of Gyration.**—Bard suggests that we can speak of the sense of gyration as a sixth sense. He shows that it has capacities for adaptation and accommodation like those of the eye and ear. The mechanism of auditory accommodation to distant sounds has a parallel in the differential tension of the two parts of the labyrinth, according to the length of the radius of the gyration. In conclusion he expatiates on the sensations of an emotional order which complete the gyration images. These explain the close connection with the rhythm of sounds, the solidarity of music and dancing. There may yet be developed, he adds, a *musique de la gyration* which will take its place beside the *musique de l'audition*. The perceptions from the sense of gyration have a wide range, from the soothing cradle-rocking to the malaise of seasickness. Like the centers for vision and for audition, the centers for gyration are sensory-motor, and those located in the cortex are closely connected with others in the cerebellum. This connection explains the nature of nystagmus, which is a double reflex action, both cerebral and cerebellar.

55. **Prophylaxis of Goiter.**—Roux insists that goiter can never be cured; when the goiter is recognized it is already too late. Hunziker's idea that goiter is the result of iodin deficit has much to sustain it. An open bottle of tincture of iodin beside the bed at night might yield enough iodin to supply this deficit. Or the schools might have some arrangement to iodize the air in the rooms. Infinitesimal amounts are all that is necessary, and these amounts are the only ones that are harmless. Other measures, addressed to the individual, come too late, Roux reiterates; they are badly managed and often they are dangerous. Goiter must be prevented before any one discovers that the child is a candidate for goiter. Iodin treatment in any form causes loss of flesh, and the still sound parts of the thyroid shrink with the goiterous portion. The immediate symptoms are relieved, and physician and patient are content; no one thinks of connecting disturbances later with the over-zealous treatment.

56. **Extension Forceps.**—A weight is suspended from a chain fastened to the handles of the padded forceps made like ice tongs. The forceps grasp the heel. It is proving a great help in applying a plaster bandage.

57. **Sigmoid Diverticulitis.**—Krafft describes several cases of what seemed to be appendicitis on the left side in elderly persons. Roentgenoscopy explained the disturbances as resulting from an inflammatory process in a diverticulum on the left side. A bismuth or barium suspension has to be injected per rectum as well as taken by the mouth for instructive roentgenoscopy. The chronic course, obstruction and hemorrhages may suggest cancer, and there may be perforation into the bladder. A liquid diet and local application of heat may suffice in some cases, watching over the patient for signs of malignant transformation. Stenosis or acute peritonitis may demand an exploratory laparotomy or artificial anus.

Correspondenz-Blatt für Schweizer Aerzte, Basel

58 The Declining Birth Rate. H. Guggisberg.—p. 1233.
59 *Mumps Pancreatitis. K. Zimmerli.—p. 1245.

Sept. 21, 1918, 48, No. 38

60 *Influenza; E. Lenz.—p. 1265; P. Demiéville.—p. 1270.
61 Sarcomatous Leiomyoma of Stomach. R. Fritzsche.—p. 1273.
62 *The Suprarenals in the Severely Burned. T. Nakata.—p. 1283.

59. **Mumps Pancreatitis.**—Zimmerli relates that about 25 per cent. of seventy soldiers in a recent epidemic of mumps presented nausea, loss of appetite and tenderness in the epigastrium. These symptoms were so intense by the sixth day in one case that they led to the discovery of pancreatitis as part of the clinical picture. The enlarged and tender pancreas showed vigorous pulsation from the aorta, but in a second case this phenomenon was not observed. It is probable that participation of the pancreas is responsible for the epigastrium symptoms in mumps. There seems to be a tendency to bradycardia in mumps, but none of the men showed any signs of nephritis. A child of 7 developed suddenly acute hemorrhagic nephritis during convalescence from mumps, but it subsided completely in a few days.

60. **Influenza.**—Lenz relates that he tried to have cotton and gauze masks used in his service at Davos during an epidemic in the winter of 1914-1915. They were made on the principle of an ether mask, and proved successful in preventing infection, but the personnel did not take kindly to the innovation. These masks were later used in some Swiss military hospitals. He suggests the possibility that the influenza virus may enter through the conjunctiva.

Demiéville remarks that the war is undoubtedly responsible for the virulence of influenza this year, on account of the repeated passage of the virus through different members of the hosts of men crowded into camps, etc., flocks of refugees, and crowds of industrial and other workers. He warns of the danger from giving drugs with a depressing action, including alcohol, and remarks that the out-of-bed management of pneumonia, strange to say, has always been extolled more by surgeons than by internists. He advocates emphatically, especially when the heart is irregular, to keep the patient sitting up in bed, or in an arm chair, for four or six hours a day—always, of course, having him lifted, without active cooperation on his part.

62. **The Suprarenals with Severe Burns.**—Nakata found the suprarenals evidently suffering from severe toxic action in cases of severe burns in human beings and in guinea-pigs and rabbits. There is evidently severe functional disturbance, sufficient possibly to explain the fatal outcome in some cases.

Gazzetta degli Ospedali e delle Cliniche, Milan

July 11, 1918, **39**, No. 55

63 *Suture of Wounds of Face. A. S. D'Emidio.—p. 534.
64 *Plastic Operation on Lower Lip. D. De-Francesco.—p. 538.

July 14, 1918, **39**, No. 56

65 Citelli Cell in Mastoiditis. P. Caliceti.—p. 544.

63. **Primary Suture of Lacerated Wounds of the Face.**—D'Emidio recalls that with fracture of the bones in the face, the natural cavities offer exceptionally favorable conditions for drainage at a low point. Hence the skin can be sutured at once in case of a war wound of the face, and the esthetic outcome compensates for the risk. He makes an opening into the adjoining natural cavity, if such does not already exist, and reports two cases which emphasize the advantages of immediate primary suture in these conditions. In both his cases the wound had been incurred the day before.

64. **Plastic Operation on Lower Lip.**—Illustrations are given of a case in which removal of a cancerous nodule just below the lower lip left an almost square hole, the angles at side and top. One of the tongue-shaped pieces of skin above, including the lip, was drawn to slant downward, to fit into the gap below the opposite corresponding flap. This left merely a linear gap shaped something like a Z. The skin was easily drawn up to close this gap, and the detached mucosa of the lip flap utilized to reconstruct the lip. The angular linear scar is now scarcely perceptible, a year later.

68 *Silver Nitrate Neutralizes Mustard Gas. G. Amantea.—p. 893.
69 *Modified Technic to Induce Pneumothorax. E. Curti.—p. 895.
70 Skeletal Anomalies and Traumatic Lesions. E. Bussa-Lay.—p. 897.

66. **Plastic Motor Surgery.**—Egidi describes three cases which demonstrate conclusively the ease and simplicity of plastic operations to supply a tunnel lined with sound skin in a position to utilize the muscular energy left in the stump. Two illustrations show the methods.

67. **Treatment of Chronic Urethritis.**—Fazzari applies a cylinder, cut out of a sponge, to the metal catheter, just below the rounding tip. This applies the medication exactly where it is needed and holds it there. The sponge does not show on the catheter as it is covered by a shell. This is removed in two parts when the catheter is in place, as is shown in the illustration. The elastic sponge dilates the urethra and scrapes it clean as the sponge is withdrawn at last. This exerts also a kind of massage, and the *irrigatore porta-spugna* has proved very useful in several years' experience with it.

68. **Silver Nitrate Neutralizes Mustard Gas.**—Amantea is assistant director of the Physiology Institute at Rome, and with many others he has been testing various means to combat the effects of the poisonous gases used in warfare. He has found that a 3 or 5 per cent. solution of silver nitrate seems to modify yperite or mustard gas—dichlorodiethylsulphid—to the point of annulling its toxic action. It does this even when the yperite has been some time in contact with the skin, following the yperite down into the depths of the tissues. He states that even with eye lesions from the yperite, the nitrate solution has proved effectual, but should be used for this in a weaker, 1 per cent. solution for instillation in the eye, or a 0.25 per cent. solution to rinse the eye with and to rinse out small wounds after thorough rinsing with water. With large wounds, a 1 per thousand solution can be used with proper caution. His research was done on animals and on himself. The mustard gas or fluid fastens to the superficial tissues at first and only very gradually works its way inward. The silver nitrate has a similar penetrating action, and in his tests neutralized the poison of the yperite when applied for ten or twenty minutes from one to nine hours later. He warns that the yperite should not be washed off with ether, chloroform or alcohol, as these promote its diffusion in the tissues.

69. **Induced Pneumothorax.**—Curti gives an illustrated description of his modification of the ordinary apparatus for artificial pneumothorax. With it the oxygen of the air is absorbed, leaving the nitrogen for injection.

Riforma Medica, Naples

71 Dilatation of Pulmonary Artery Revealed by Roentgen Rays. L. Coleschi.—p. 706.
72 *Serotherapy for Surgical Infections. R. Mosti.—p. 709.
73 *The Prevailing Epidemic. G. Sofre.—p. 712.
74 Pyogenic Dermatitis. V. Chirivino.—p. 714.
75 Status of Treatment of Cholelithiasis. E. Aievoli.—p. 715.
76 Status of Epidemic Poliomyelitis. G. Molinari.—p. 717.

72. **Serotherapy in Surgical Infections.**—Mosti relates that he long ago abandoned hypochlorite solutions and all other antiseptics as he obtained far better results with the polyvalent serum made by Lanfranchi and Finzi with many strains of microbes, not excluding anaerobes. He applies the serum locally by the Carrel technic in recent wounds without phenomena indicating sepsis. When there is sepsis, he administers it also by the subcutaneous or intravenous route. The surgical clearing out of the wound must be minutely thorough to begin with. Then the polyvalent serum displays a preventive and curative action against pyogenic bacteria, while it seems to exert a pronounced histoplastic action besides, stimulating tissue repair and permitting early secondary suture. He urges that the advanced posts should be supplied freely with this serum to use it copiously from the very first. He has had no mishaps with it, and all his experience points to its superior efficacy over antiseptics or any other method of treating wounds. The serum is made like the French Leclainche-Vallée serum, originally designed for veterinary use, but more strains of bacteria are used in its preparation. The effect is better in the recent, acute cases. Conditions in the knee are less favorable for this or any treatment than in other joints.

times most prominent in the liver region, sometimes over the pancreas. With the former they spread to the right shoulder, with the latter to the lumbar region. They came on two or three hours after eating, a sensation of oppression or violent colics with passage of large amounts of gases. Nausea was frequent but vomiting was rare; diarrhea may alternate with constipation. Tympanites two or three hours after eating is a prominent symptom, and deep palpation may reveal tenderness in the duodenal zone. There is a tendency to a muddy complexion, malaise, somnolence, muscular atrophy and weakness, possibly also alimentary glycosuria, and the urea content is reduced as also the proportions between the total sulphur and the incompletely oxidized sulphur. We thus have it in our power now to detect duodenal dyspepsia with a precision hitherto unknown, and thus apply suitable treatment.

42. **Technic for Study of Duodenal Functioning.**—Gaultier uses Fouchet's sensitive test for bile pigments, and pancreatin for testing the pancreatic power. He describes the technic, believing that it has a future, being more exact than Einhorn's method.

43. **Addison's Disease.**—The typical case reported was distinguished by the lesions of the solar plexus and the fact that the suprarenals were free from tuberculosis.

44. **Bacteriotherapy Plus Serotherapy in Meningitis.**——Florand and Fiessinger report a case in which serotherapy for two strains of meningococci failed to benefit as a third strain was involved. An iodized autogenous vaccine was then used, and prompt recovery followed as also in two other cases described, in which the vaccine and serotherapy were used together. In the discussion that followed, Netter related that intramuscular injections often prove useful to supplement the intraspinal in case of meningococcus septicemia. He has also had encouraging results with vaccine therapy in cases rebellious to serotherapy.

of the patients being left with fistulas and one with a suppurating epididymitis. On the other hand, in five cases in which the suprapubic route was followed, the immediate and the remote results have been fine. The perineal technic has several disadvantages, among them the necessity for leaving a bridge of prostatic tissue. This remnant of tissue may serve as the source for renewed growth, while its presence prevents the bladder from regaining normal tone.

90. **History of Medicine in Mexico.**—Leon's data refer to the period after the university had been founded in 1553 and a medical department organized in 1582. The various documents, theses, etc., have been mostly preserved, and they throw light among other things on the American origin of syphilis. This is sustained by the sudden introduction of descriptions of syphilis into the medical literature at the close of the fifteenth century. There is no proof, however, that the syphilitic lesions found in ancient bones in America date from before Columbus' day. On account of the humidity in Mexico, very few prehistoric bones are found there, and as the burial places have been used for centuries since then, it is impossible to set any date for them. The same may be said of the descriptions of syphilitic lesions in the early Spanish writings in Mexico. The main work of one of these early Spanish writers, Juan de Cardenas, dated 1591, has recently been republished by the Museo Nacional of Mexico. He says of syphilis that nowhere in the world are its ravages so common or so severe as "in the Indias," meaning Mexico. . . . "It reigns there as if it were the fruit of the soil." He adds, "The nature of this contagious *mal de las bubas* is unknown, but it is not a modern disease. It is new to Europe, but I imagine that the Indians here have had it ever since they occupied the country, as it seems to be inherent in the land here on account of the heat and humidity." . . . "The Indians say that a man without some trace of this disease is not an honest man. It is so common here that the absence of bones in the face scarcely attracts a glance." The Inquisition was introduced into Mexico in 1571 and all books brought into the country had to be registered, and the shadow cast by the Inquisition checked the progress of medical science both in Old and New Spain. In 1592 the viceroy of Mexico complained to the king of Spain that "so many useless emigrants were sent out from Spain, *medicos y literatos,* when the demand was for *agricultores e industriales.*" Cortez founded a hospital in 1524, placing it in charge of a religious brotherhood, and the early foundation of more than thirty-six others is mentioned.

92. **Plotz' Alleged Typhus Bacillus.**—Fabela was unable to cultivate from the blood of fourteen typhus patients any bacilli resembling in the least Plotz' *Bacillus typhi.*

93. **Gonorrheal Joint Lesions in Infants.**—Prieto reports the cases of three infants of from 5 to 20 months old, with a catarrhal urethritis and multiple joint disturbances. The latter promptly subsided under immobilization alone. The gonococcus was found in the urethra or vulva.

Prensa Medica Argentina, Buenos Aires

97 *Cystic Sarcomas. P. M. Barlaro and A. Buzzi.—p. 89.
98 Atypical Degeneration of Retina in Adult. E. Dameno.—p. 90.
99 *Syphilis with Gastric and Duodenal Ulcers. R. E. Parody.—p. 91.
100 *Syphilitic Banti's Disease. L. L. Resio.—p. 92.

97. **Cystic Sarcoma of the Liver.**—Barlaro and Buzzi have been unable to find on record any case resembling the one they describe. The primary sarcoma was in the ovary, and the metastases in liver and lung were of a cystic type. The cystic tumors looked like giant graafian follicles, as is evident in the four illustrations.

99. **Inherited Syphilis in Etiology of Gastric Ulcers.**—Parody refers to Castex' recent publications on this subject as of fundamental importance. His views were summarized recently on page 320. Parody reports two cases as further evidence of the causal connection between syphilis and gastric ulcer. A young woman had a gastric ulcer and hematemesis, and investigation then revealed signs of inherited syphilis. Her mother had also had hematemesis on several occasions since puberty, and presented various signs of acquired syphilis. The rapid improvement in the daughter under specific treatment confirmed the diagnosis. For fear of bringing on the hematemesis anew, Parody gave calcium chlorid as a preliminary to the mercurial treatment.

100. **Banti's Disease in a Syphilitic.**—Resio argues that the prompt subsidence of the Banti syndrome under treatment as for syphilis testified to its syphilitic origin.

Revista de Medicina y Cirugia, Havana

Aug. 10, 1918, **23**, No. 15

101 Bacteriotherapy in Typhoid Group. M. M. Dominguez.—p. 409.

102 *Results of Operations on Biliary Apparatus. J. A. Presno.—p. 439.
103 *Elephantiasis. V. Pardo y Castello.—p. 449.

102. **Remote Results of Gallstone Operations.**—Presno remarks that the principal function of the gallbladder seems to be merely to maintain the balance of pressure in the bile passages. This function can be readily assumed by compensating dilatation of the common bile duct. This has evidently been the case in 18 of his 67 cholecystectomy cases, as there has been no disturbance of any kind from the loss of the gallbladder during the interval of five years or more since the operation. The group includes three women who have passed through normal pregnancies since. In another group of 21 cases, the cholecystectomy was supplemented by operations on the bile ducts, and in no instance have there been any disturbances from the bile apparatus since. In another case, chronic pancreatitis hampered the functioning of the sound biliary passages, and he implanted the gallbladder in the jejunum. All the symptoms, including those from the pancreas soon subsided to permanent recovery. The theoretical danger of ascending infection does not justify, he thinks, needlessly complicated operations in such cases. This patient has been in excellent health during the year to date. In conclusion he reports a case of what seems to be actual recurrence of gallstones.

103. **Elephantiasis.**—One of the three cases illustrated presents various manifestations of filariasis besides the elephantiasis, including chyluria and chylocele. The arms are the main seat of the elephantiasis in this case; in the third case, the scrotum. It reaches 10 cm. below the knees of the tall man.

106 Relations between the Pathology of the Skin and Internal Pathology. D. E. de Oyarzabal.—p. 193.

104. **Pancreatic Retention.**—Urrutia reports two cases which warn that the absence of the pancreatic ferments from the stools does not inevitably imply insufficiency of the pancreas. The outlet may be merely blocked; the amylase thus disappears from the stools and appears in the urine. The pancreas may become insufficient later from the disturbance in the circulation and sclerosis, but even with a cancer in the pancreas, the sound portion of the pancreas may long function perfectly.

107. **Prophylaxis of Anthrax.**—The Sociedad de Medicina of Montevideo appointed a committee of three to study this question, and their report is an able summary of the present status of our knowledge of malignant pustule and means to avoid it. They regard as indispensable for prophylaxis the compulsory vaccination, by experts, of all animals susceptible of contracting anthrax. A certificate of vaccination should be exacted in sales of cattle and products from them, and other measures should be adopted to ensure this. They give a

circular to be posted in workshops, etc., warning of the danger of anthrax as a very grave and frequently fatal disease, and how it is acquired, and how avoided. The neck should be protected against it with special care, as the pustule is particularly dangerous in the neck. They describe a protecting device to be worn when handling hides, which protects against this. The committee refer in conclusion to certain ranches, etc., where vaccination has amply demonstrated its usefulness, without mishaps of any kind, and they reiterate that anthrax will be eradicated when all the susceptible animals are vaccinated. On the other hand, it now is increasing at an alarming rate.

109. **Echinococcus Cysts of the Lungs.**—Legnani's ten cases teach that this disease should be suspected whenever hemoptysis, small or profuse, develops without anything else to suggest pulmonary tuberculosis or embolism of cardiac origin, even when there is no primary cyst in the liver or elsewhere, and no stethoscopic or radioscopic findings on a single examination. He is convinced that many cases of echinococcus cyst escape detection, and he urges search for signs of it in the sputum, as many pulmonary processes, congestion, pleurisy, chronic bronchitis, etc., may be based on an echinococcus cyst, and simulate tuberculosis by their persistency. The entire absence of signs and symptoms beyond the hemoptysis was most striking in some of his cases, especially in the four boys, 10 to 15 years old, but also in some of the adults. He operated in all the cases, except those with spontaneous vomica and one in which the hemoptysis proved fatal. All the patients were cured at once.

110. **Lethargic Encephalitis.**—Morquio reports three cases which fit into the clinical frame of lethargic encephalitis as described by Netter, recently, in Paris and by Economo in Vienna in May, 1917. His patients were two girls of 10 and 12, and a boy of 13. All were taken suddenly with headache, fever, convulsions and unconsciousness, the stupor persisting till death the fifth and twenty-third days in the two girls. The boy recovered after a period of lethargy with slight meningeal reaction. Necropsy revealed a congestive and inflammatory process in the brain, superficial and diffuse, with apparently normal cerebrospinal fluid. There was no meningitis, no tumor. One of the children slept constantly as if in normal slumber, except for the ptosis and diplopia, headache and general depression, but no general disturbances and no fever. The somnolency gradually became actual coma, with death the twenty-thrd day. Tuberculous meningitis was excluded in all by the apparently normal lumbar puncture fluid. Another child presented a somewhat similar picture with somnolency predominating, but necropsy revealed a tumor of the pituitary body.

116 *Treatment of Burns. H. Gregorini and O. Ivanissevich.—p. 708.
117 *Gastro-Intestinal Disorder in Infants. R. Cabrera and T. Scannavino.—p. 712. Commenced in No. 17, p. 465.
118 *Campaign against Tuberculosis. E. R. Coni.—p. 721.

115. **History of Hygiene in Argentina.**—This is the prologue to Coni's book, now on the press, "Memorias de un Medico Higienista." As he was official statistician and a pioneer in matters of public health and demography, as well as in medical education and administration, Penna says that his simple memoirs form practically the history of public hygiene in Argentina.

116. **Film Treatment of Burns and Leg Ulcers.**—Gregorini and Ivanissevich extol the benefits of film treatment of burns, relating several instances of rapid healing under the protecting film. They incorporate some methylene blue in the film they use, but do not give the formula. Leg ulcers rebellious to all other measures for months healed smoothly under it in about a month. After a hemorrhoid operation, the tube to be introduced for flatus is coated with the film, and the anus is covered with it around the tube. It is also useful after circumcision.

117. **Digestive Disturbances in Young Children.**—This serial article discusses the clinical picture with overfeeding, specific enteritis, etc. The writers emphasize that the statistics do not reveal all the mortality from injudicious feeding of infants, as the deaths are attributed to intercurrent diseases which the children might easily have weathered if they had not been so debilitated by the digestive disorders. They reiterate that the ignorance of the mothers is the main thing to be combated, and the only way to do this effectually is to teach in the schools the proper care of infants, impressing it on the schoolchildren by repeating the course and amplifying it year after year. Courses for adults should also be organized, as the most important and necessary part of hygiene is that which corresponds to alimentation of all ages. What is learned in childhood makes the most impression, and the lessons of puericulture and hygiene then inculcated will bear the most fruit.

118. **Campaign Against Tuberculosis.**—Coni reiterates that the campaign against tuberculosis is a function of the state, and that the national, provincial and municipal authorities should all take part in it. In order for it to be efficiently managed, the authorities should place the management in a single hand.

121 *Practical Ophthalmology. D. J. and D. E. Wieden.—p. 639.

119. **Blood Changes and Gastric Ulcer.**—Carro rejects the assumption that hyperchlorhydria is the main factor in gastric ulcer, as ulcer may occur without it, while it may exist without development of ulceration. The composition of the blood and conditions of circulation seem to have more influence on gastric cancer than any other factor. The differential blood count may throw light on the intensity of the process and on the prognosis.

120. **Oxygen in Treatment of Rheumatism.**—Zabaleta reports that subcutaneous injection of oxygen has been systematically applied for several years and in thousands of patients with different forms of rheumatism, mostly subacute and chronic, at the dispensary in his charge. These experiences, he declares, have established the efficacy of this technic. It is a powerful adjuvant to other measures, and it is absolutely harmless with care to refrain from piercing a vessel. He usually injects 100 c.c. at the site of the pain, sometimes injecting all the larger joints at one sitting, using up 2, 4 or more liters. The blood afterward shows an increase in the reds and hemoglobin, and there is an increased output of urine and its urea content. A few examples are cited to show the great relief afforded, even in severe cases of long standing. One elderly woman with chronic nodular rheumatism for two years in hands and knees was relieved of all pain and inflammation by eight injections of oxygen. The urea output increased by more than double. The oxygen was injected into the dorsum of the hands and was massaged into the fingers. Rheumatic sciatica for two months in an elderly man yielded to ten injections at three day intervals; the improvement was pronounced after the first injection. The injections were made at the points of severest pain, the sciatic foramen and the popliteal and malleolar regions. In many cases of deforming rheumatism the disease seemed to be permanently arrested, besides the relief of all pain.

121. **Practical Ophthalmology.**—Wieden relates experiences with Barraquer's aspiration extraction of cataract in the capsule. He regards this technic as "one of the greatest achievements of surgery of the eye in current century, as it realizes the ideal operation for which all have been longing." (It was described in The Journal, June 9, 1917, 1789.)

THE SPECIALIST'S RELATION TO THE AMERICAN MEDICAL ASSOCIATION

AND A PLEA FOR GENERAL GORGAS' RETENTION IN OFFICE *

GREENFIELD SLUDER, M.D.
ST. LOUIS

When I was elected to this most important and flattering position last year, I felt that there were so many others that could have served the purpose better, that I was sorry for it, but as the year has gone by, I have felt more and more that my privilege was a very high and sacred one, and have done the best I could to merit it.

Rarely, I think, has a chairman had matters of such importance to present to the section. I have two subjects of the greatest interest to all medical men, namely, the position in which the Army medical service at present finds itself,[1] and our relation to the American Medical Association.

SECTION DIFFICULTIES

The second subject that I bring to your attention is our relations with the American Medical Association. I say our relations, by which I mean those of otolaryngologists and ophthalmologists. It seems that, according to the categories of the Association, we are the only ones thought of as specialists; or at least that is the impression that I get from reading the proceedings of the House of Delegates in New York City last year.

So we, as specialists, have a problem to present to the Association. In fact, however, almost every practitioner at the present time, at least the successful professional men in the larger cities, are, in reality, specialists. The whole field of medicine now-a-days is an absolute physical impossibility for any one man to compass satisfactorily and permit himself to say that he can do it all.

The specialties now include not only gynecology and genito-urinary surgery, formerly considered in the same section, but also gastro-enterology, etc.

The number of sections in the present meeting is fifteen. Each of these sections may be said to be a special section; but for some reason, the Trustees have not considered it so, and have selected us as men more or less outside the pale of interest for the general practitioner; and because our papers are "of no interest to the general practitioner," they propose to leave us out of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

We shall be permitted to meet as a section of the Association, to transact as much or as little business as we please; but our proceedings are to be ignored, as *they put it on* the ground that the cost of THE JOURNAL has increased very greatly. Later, they *passed a resolution declaring all section papers voluntary*, and to be edited.

That the cost of everything has increased greatly is familiar to all of us—painfully so. THE JOURNAL has shared in this increase, which might also be shared by us, just as we share in bearing the increased cost of everything else. If the cost of THE JOURNAL is beyond the subscription price of $5 at the present time, as a matter of business there can be no possible reason given why the price of THE JOURNAL couldn't be raised somewhat to meet the necessities of the publication at the present time. But that has not been the plan of action of the Trustees. They have elected to omit our papers, except when they see specially fit to publish one, and on second thought, to omit all other section papers they see fit.

At first thought, some of us might be indifferent to this rule, but on second thought, it seems to me that none of us can possibly be indifferent. We are medical men in sympathy with our fellow practitioners. We want to know what they are doing; and I can see no reason why we should not arrogate unto ourselves the idea that they should be interested, somewhat at least, in what we are doing.

THE CHARGE OF UNDUE TECHNICALITY

The Trustees have characterized our papers as too technical to be of interest to the general practitioner. They have also criticized the censorship exercised over the papers admitted to the program. We can readily understand that some papers may be very highly technical, and for that reason the author himself should consent to the publication, not of his full text, but of some small abstract which will point the way for the general practitioner, should he care to look the paper up. And if there is laxity in censorship, this not only might be, but should most decidedly be, corrected.

As a member of the section for a number of years, it seems to me that the papers presented before this body have been almost uniformly good, and worthy of presentation and of our time spent in listening to them.

---

* Chairman's address, read before the Section on Laryngology, Otology and Rhinology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Concerning this subject statements were made relative to the retention of General Gorgas as surgeon-general. These are omitted from THE JOURNAL since General Gorgas was retired in October, having reached the age limit. The complete text appears in the Transactions of the Section.

The idea of being outcasts from the pages of The Journal seems to me such a calamity for us that I feel that special emphasis at this time should be laid on what The Journal of the American Medical Association is, and what are its possibilities for us.

Firstly, there is no journal in the country that reaches anything like the number of men that The Journal of the American Medical Association reaches. It is the only general journal; all the other journals are more or less local affairs. A parallel has been drawn between our country and Great Britain. This doesn't seem to me to be exactly a thing permitting argument. The Trustees have declared that the British Medical Association publishes only abstracts, and finishes them up in a very short time, possibly a few weeks.

The policy of the *British Medical Journal* is to publish the abstracts and finish them very quickly. The reader of the paper then has the privilege of publishing them anywhere. Physicians have the well known *Lancet,* in which their material may appear. There is no journal in our country that in any wise compares with the *Lancet.* We are left, then, if we have the desire to appeal to the general profession, to one journal only, The Journal of the American Medical Association.

It appears to me that this proceeding, by which we are ruled out of The Journal, is not only a disaster for us, but a disaster for the general profession. I cannot agree with the Trustees in their point of view, although I recognize by their names that they are a most estimable and intelligent body.

When they say that our work is of no interest to the general practitioner, they overlook the fact that almost all the general practitioners and general surgeons of the entire country at the present time will remove tonsils and adenoids if they have the opportunity of doing so, or at least they will try to remove them. They will also perform all the intranasal surgical operations that their intelligence permits them to suggest to the patient; and from an observation of such patients after having been operated on by the general men, we must all be struck with the idea that, if the general practitioner knew more about this work it would be not only to his advantage, but even more to the advantage of the patient. Many of the unfortunate results from which the patient suffers would be avoided. If the general practitioners are to continue in the practice of nose and throat surgery, then it behooves us from the same altruistic motive so emphasized by The Journal itself, as part of its plan of action, to educate the general profession as far as possible further along the line of the specialties for which they operate. Therefore, it is impossible to understand how any intelligent medical man can declare that the work of the eye, ear, nose and throat sections is of no interest to the general profession.

The Trustees have emphasized the fact that the papers are technical. Every now and then, it is true, there comes out a perfectly simple technical paper—a record of facts; but facts can never be properly valued at the time they are presented. Nevertheless, the record of a new fact is always justifiable.

A SPECIALIST'S DISCOVERY OF GENERAL INTEREST

Nothing can more clearly emphasize this point than the work of my friend, Dr. W. E. Shahan of St. Louis, who, four or five years ago, began the investigation of the effect of heat on the eye. He determined the cornea would stand a certain degree of heat without detriment. He then took up the question, "What is the degree of heat at which the various organisms are killed in the tissues?" and by experiment he found that at a temperature of 156 F. the pneumococcus was killed within the cornea. He devised a machine by which heat could be very accurately controlled, and this temperature applied to the ulcers of the cornea. It is perfectly well known that the pneumococcus is one that destroys the globe in the great majority of instances.

Through this bit of observation, Dr. Shahan has determined that the pneumococcus ulcer, heretofore so destructive, can be satisfactorily controlled in almost any case, as I understand it; and when the ulcers are beginning to form they are stopped and cured. The number of eyes that have been saved by this practice is unlimited.

The discovery has been turned to use for other purposes also, in other departments of ophthalmology. All of this was published in The Journal.

It is impossible for me to understand how an observation such as this can fail to be of interest to the general practitioner. It seems to me that if facts of this type cannot interest him, he is an exceedingly poor, low-grade sample of his kind. That there were such practitioners some years ago is perfectly well known; but certainly, as the years go by, that number diminishes. The men who replace them are of a different type. They are infinitely better educated, and of infinitely wider interests, not only in medicine, but in human affairs at large. Furthermore, the minute their interest in such observation is aroused, the working method by which such an end-result is obtained, would be worth, I should think, an inestimable figure to them.

Many of us would like to do original work, and we admire the men who do; but when, on asking ourselves, "Why don't we do it?" we admit to ourselves that we have no ideas. To follow the working of such an idea as that of Dr. Shahan must surely be a help and an inspiration to all who have any aspiration toward original observation.

Previous to Dr. Shahan's idea, various efforts had been made to apply heat to the eye for therapeutic purpose; but the fact that it was not known at what temperature the cornea or bacteria within the cornea were killed worked for the failure of these attempts.

It seems to me that with the difficulty now confronting the management of The Journal, we should all be sympathetic.

As a suggestion by which all may feel that they have fair play, I see no reason why a certain number of pages should not be allotted to each section, and these portioned out as may seem best to the authors on the program, by officers of the section. This would relieve the editorial staff of much work and would relieve us of the feeling that our affairs are possibly in the charge of a staff that is not only inimical to us, but ignorant of our rights as scientific medical men. It would give each section the best opportunity to maintain the high value and standard of The Journal, independent of its able editors and trustees.

ABSTRACT OF DISCUSSION

DR. WENDELL C. PHILLIPS, New York: I have taken pains to find some remedy for the situation which confronts not only this section but all of the sections of the Association. Talking will never accomplish anything. We must take more active measures to get at the facts. There are two sides to the situation, and many difficulties present themselves to the trustees in the management of this great American Medical Association. I have been simply amazed at the responsibilities as well as the care and the thought that is necessary in order that the work of the Association may be carried on well and that we may properly represent the membership.

I will suggest this, that this section and, if possible, the Section on Ophthalmology, appoint a committee with instructions that they consult with the Board of Trustees regarding the quesion of the publication of papers and to give the proper publicity to the papers read before this section and the Section on Ophthalmology. If you will look over the program you will have no difficulty in seeing that even in THE JOURNAL it would be impossible to publish all the papers and discussions together with the other things we are expected to publish during the year. It simply cannot be done, so that some censorship and care has to be taken, and some papers must be eliminated. But I do feel that an effort should be made—and usually it can be done if it is done in the right way—so that the sections and the central officers may have a proper understanding and adopt the best possible plan. I may say, however, that in so far as the specialties have adopted special journals under the auspices of the Association, general satisfaction has been obtained.

DR. L. W. DEAN, Iowa City, Iowa: Last year the executive committee of this section was instructed to confer with the Board of Trustees in regard to the publication of papers read before this section, and there also is a committee from the section to report on the method of publication.

DR. WENDELL C. PHILLIPS: So far as I know no such matter has been brought before the Board of Trustees during 1918.

DR. GREENFIELD SLUDER, St. Louis: Dr. Phillips has been exceedingly helpful in giving us some needed information. The procedure by which we were outcast was one in which we had no part and in which we were denied a part. When I stated that the difficulties of THE JOURNAL should be considered sympathetically, I meant precisely what I said—I selected the term to the best of my ability.

Carbon Tetrachlorid Vapor as a Delousing Agent.—M. H. Foster, Surgeon, United States Public Health Service, in *Public Health Reports*, October 25, makes a preliminary report on experiments for the killing of lice in the clothing by the vapor of carbon tetrachlorid. Heat and hydrocyanic gas are probably the best agents for killing lice but require somewhat complicated apparatus for their use and can be used to advantage only where the work is to be done on an extensive scale. The object of the experiment was to find some agent that could be used practically anywhere and for small operations. It was found that carbon tetrachlorid vapor was effective after two hours' exposure with the clothing rather closely packed in a tin or other vessel that is air tight, in an amount of 25 c.c. The material to be disinfected should not occupy more than half or two thirds of the containing vessel. In the experiments only the lice were killed. The nits were only partly killed, but their hatching was delayed. The method used was simply to pack the material to be disinfected in the can, on top of which were placed several layers of filter paper on which was poured the carbon tetrachlorid. The can was then covered with several thicknesses of toweling and a loose cover placed over this. In some experiments, the lice infested material was wrapped up tightly in papers, etc., and various combinations of carbon tetrachlorid with gasoline, were tried. The unadulterated carbon tetrachlorid was found to be best and the lice were always killed in about the time mentioned. At the present price of carbon tetrachlorid, the cost for treatment of the clothing of one soldier will amount to from 1½ to 5 cents.

ACROMEGALY OF THE LARYNX *

CHEVALIER JACKSON, M.D.

PHILADELPHIA

The literature of acromegaly contains but little reference to the larynx, which seems strange in view of the fact that in a number of cases alteration of the voice is mentioned. I hope that the herein recorded cases will lead to systematic examination of the larynx not only in every case of acromegaly but also in every case of hypophysial abnormality. It is to call attention to the necessity for this that the four cases are reported. Complete reports of all the cases would require too much space and would detract from the emphasis desired to be placed on the laryngeal phases:

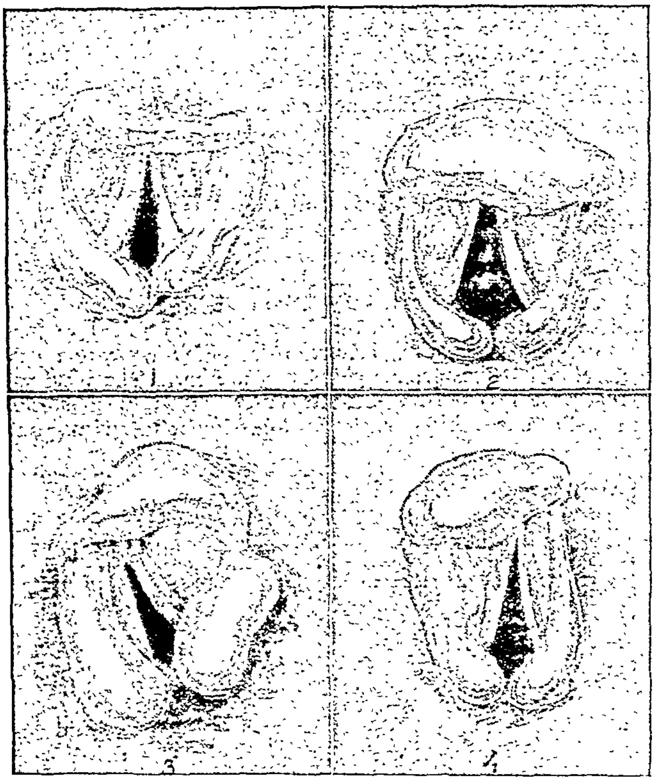

Fig. 1.—Acromegaly of the larynx. The enlargement and thickening of the various prominences of the larynges are bilateral. The asymmetry seems rather a distortion, though at 4 is shown a larynx with elongation of one aryepiglottic fold associated with thickening of its fellow. The larynx shown at 3 was so suggestive of the typical acromegalic hands as to merit the appellation of "gingerbread larynx." The whole larynx by external palpation seemed symmetrically enlarged in all cases except the one shown at 2, in which the overgrowth was limited to the epiglottis.

REPORT OF CASES

CASE 1.—*History*.—A man, aged 43, complained of remittent shortness of breath of two years' duration. Breathing was noisy at night. Repeated "asthmatic" attacks culminated in a severe dyspneic attack two weeks before. A laryngologist arrived in time to do a tracheotomy and save the patient's life. A diagnosis of laryngeal cancer was made and the patient was referred to me.

Laryngeal Examination.—External palpation of the larynx revealed it to be of enormous size, the enlargement seeming even and symmetrical. Laryngoscopic examination showed a general overgrowth of the larynx. The epiglottis, aryepiglottic folds, ventricular bands and vocal cords were proportionally enlarged. An appearance of asymmetry was given by the deviation of the long axis of the glottis, which, instead of being sagittal, was deviated to the left posteriorly (3, Fig. 1). The glottic chink was very narrow and was insufficient for breathing. The left aryepiglottic fold was as much thickened as the right, but was not so long. The whole laryngeal image was strongly suggestive of the facies (Fig. 2) and "gingerbread hands" (Fig. 3) of acromegaly. This, with the suggestive facies of the patient led to an investigation which revealed the case to be one of acromegaly, the diagnosis of which had not previously been made. Questioning elicited the fact that when 23 years of age (Fig. 4) the patient wore a number 8½ shoe, and a 15 collar. At the time of examination, twenty years later, he wore a number 9½ shoe, and a 16½ collar.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

Roentgenographic Examination (by Dr. George C. Johnston).—The pituitary fossa is 1¼ inches anteroposteriorly and 1 inch deep. There is a pressure atrophy of the posterior clinoids and of the roof of the sphenoidal sinus. The roof of the sinus is crushed in. There is obliteration of air cells, the anterior lobe of the pituitary resting largely within the sphenoidal sinus. Frontal and maxillary sinuses are very large and clear. There is but little evidence of pressure on the anterior clinoidal region; therefore the bitemporal hemianopsia which we can expect to develop later is probably not yet present. The pituitary enlargement may be expected to encroach on the posterior lobe with a resulting posteror lobe hypopituitarism, and I should expect as the disease progresses that this patient will show epileptiform manifestations. It may be that the glottic spasm for which tracheotomy was necessary was partially of this nature. The roentgenogram of the larynx (Fig. 5) shows increased density in all the cartilages of the larynx and an apparent calcification of the stylopharyngeus muscle. The superior cornu of the thyroid cartilage is also very distinctly seen to be elongated, especially the left. The patient is an acromegalic in an advanced stage, showing characteristic gingerbread hands and rough hewn face with African nose.

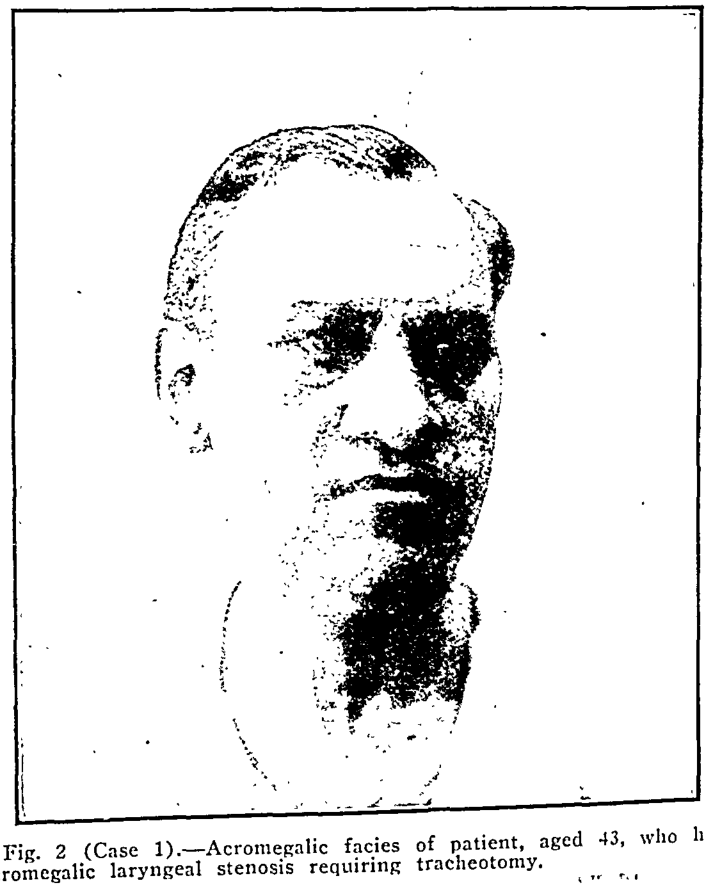

Fig. 2 (Case 1).—Acromegalic facies of patient, aged 43, who had acromegalic laryngeal stenosis requiring tracheotomy.

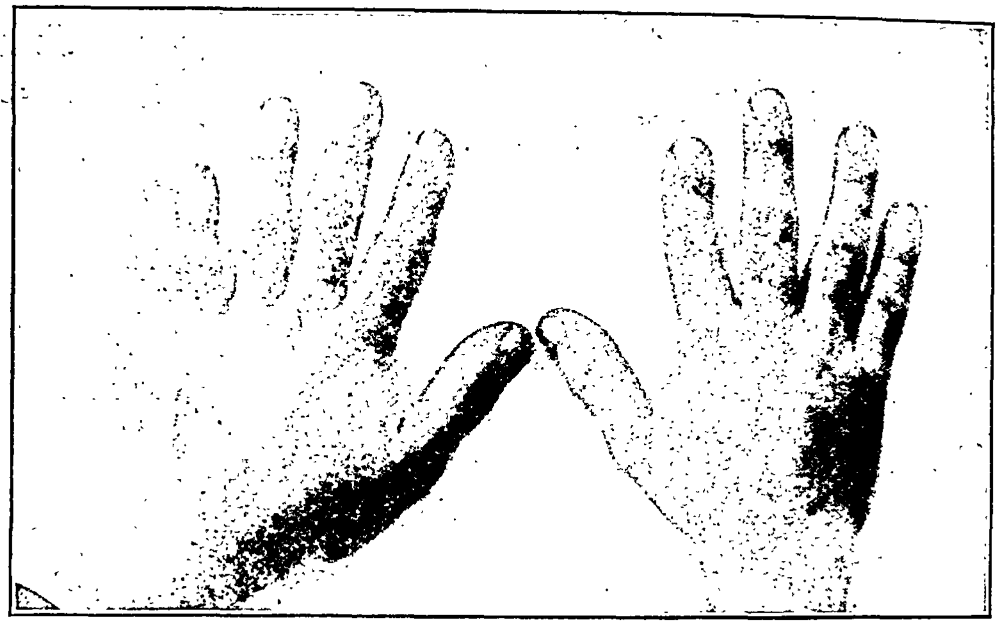

Fig. 3 (Case 1).—"Gingerbread" hands.

The attending laryngologist was advised to send the patient to Dr. Harvey Cushing for study; but before this could be done the patient died suddenly at his home, apparently of asphyxia. No necropsy was obtainable.

Case 2 (Abstract).—A minister, aged 42, was referred for laryngeal examination because of impaired voice, which in recent years had become very harsh and weak. Laryngeal tuberculosis was suspected by the laryngologist in attendance. Palpation revealed a symmetrically enlarged larynx. Indirect laryngoscopy showed the epiglottis thickened. The left aryepiglottic fold was thickened near the epiglottis. The right aryepiglottic fold was elongated (1, Fig. 1). The movement of the right arytenoid was impaired. A diagnosis of acromegalic larynx was made because of the laryngeal overgrowth covered with normal mucosa, in a man with the following general signs of acromegaly: gradual increase in the size of hat and shoes required, enlargement of the external nose, the malar prominences, and the lower jaw. These changes were sufficient to be unmistakable once attention was called to them, but they were not striking; hence the diagnosis of the general malady had not been made by the regular medical attendant. This patient was seen before the days of the usefulness of the roentgen ray in diagnosis of pituitary disease was developed.

Case 3 (Abstract).—A woman, aged 33, referred for consultation as to supposed tuberculosis of the epiglottis, had a masculine voice, and indirect laryngoscopy revealed a thickened epiglottis somewhat suggestive of the turban shape often seen in tuberculosis; but the thickening was more irregular, and all the usual appearances of a laryngeal tuberculosis were absent. The mucosa was normal (2, Fig. 1). A diagnosis of acromegalic overgrowth of the epiglottis was made on the basis of the following general signs: nose enlarged, forehead somewhat retreating, both ears enlarged, finger rings had become so tight as to require sawing to remove them. Hypophysial disease was revealed by roentgenography at Western Pennsylvania Hospital. The masculine character of the voice with a normal laryngeal interior pointed to changed resonating cavities, though of course the character of the normal male voice is partly due to laryngeal differences.

Case 4 (Abstract).—The patient was referred for supposed lupus of the larynx, the diagnosis being based largely on a scar on the nose which the patient attributed to a "boil." Indirect laryngoscopy revealed a larynx very much elongated anteroposteriorly, the left aryepiglottic fold being fully half again as long as normal, the sagittal length of the glottic chink being increased by about one third. The epiglottis was overgrown to about thrice its normal thickness, and it was tilted at an angle of about 10 degrees. The right aryepiglottic fold was overgrown in all directions with a nodular thickening near the epiglottis (4, Fig. 1). The mucosa was chronically inflamed. A diagnosis of acromegaly of the larynx was made because of the following general signs of acromegaly; facies, gingerbread hands, kyphosis, and projecting os calcis. Disease of the hypophysis was demonstrated by Dr. Russell H. Boggs.

CONCLUSIONS

Four cases are too few for final conclusions, but the following points seem important:

1. The larynx should be examined in every case of hypophysial abnormality.
2. The overgrowth characteristic of acromegaly in some cases involves the laryngeal cartilages and soft parts.
3. Acromegalic changes in the larynx may produce stenosis sufficient to require tracheotomy to prevent asphyxia, dyspnea being added to by impairment of the glottic movements, resulting in a defective bechic cycle.
4. In three out of four cases, the laryngeal mucosa was normal. In one, the chronic laryngitis present was probably a coincidence.
5. In three of the four cases, the laryngeal image was not symmetrical, though the laryngeal enlargement seemed so by external palpation.
6. In all cases of apparent hyperplasia of the larynx, acromegalic overgrowth should be listed for diagnostic exclusion.

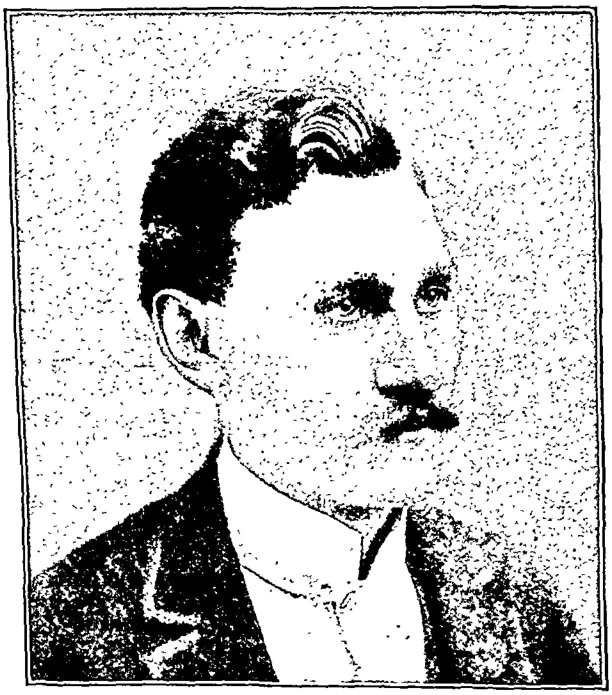

Fig. 4 (Case 1).—Patient at the age of 23.

7. Laryngeal examination should be recorded as a routine in all cases of hypophysial abnormality, for the accumulation of data.
8. Altered voice in acromegaly may be due to laryngeal changes as well as to alteration in the resonating cavities, lingual enlargement, etc.

ABSTRACT OF DISCUSSION

Dr. William B. Chamberlin, Cleveland: I would like to ask Dr. Jackson if the general signs of acromegaly are essential, and in the absence of other signs how he would differentiate these cases from rhinoscleroma?

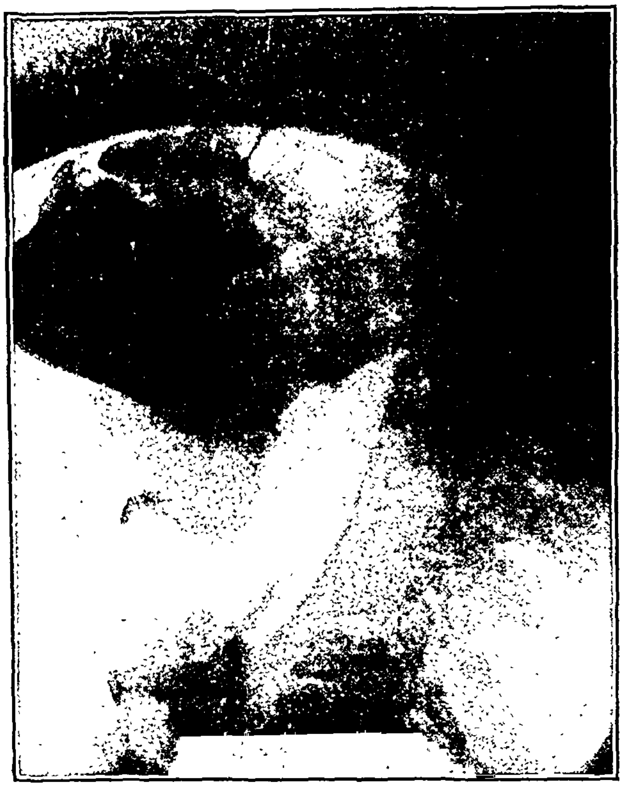

Fig. 5 (Case 1).—Overgrowth and ossification of the thyroid cartilage with extensive elongation, especially of the left cornu. (Roentgenogram by Dr. George C. Johnston.)

Dr. Chevalier Jackson, Philadelphia: Dr. Chamberlin brings out an exceedingly important point and I wish I could answer it. It has often been said of medical men that they get one case and make sweeping generalizations from it, and we often do. In this instance, there are only four cases, and, therefore, broad generalizations seem unjustifiable. I do not believe anybody could make a diagnosis of acromegaly by laryngoscopic examination alone: it would require the corroboration of the general symtomatology. As to the local points of differentiation between laryngeal acromegaly and rhinoscleroma, I feel that Dr. Chamberlin has raised an important point, but one that I cannot answer on the experience of only four cases.

For the present we must rely on the symptoms outside the larynx.

Removing Joint and Muscle Disabilities.—It is of the utmost importance to understand the use that can be made of a man's sound limbs to enable him to recover the use of an injured one. Attention is too much centered on obtaining some anatomically correct movement; meantime all the other limbs are allowed to remain inactive, and if the anatomically correct movement cannot be obtained, then the case is given up as incurable. Such concentrated treatment ignores the value of associated movements of joints brought about by the muscles passing over one or more joints. Take the case of a man who cannot flex one joint of the upper or lower limb, or who can only partially flex a joint. In addition to any special effort to flex that joint singly, it is important to get him to flex all the sound joints of the limb, which all tends to make him capable of flexing the injured one.—Col. H. E. Deane, Gymnastic Treatment for Joint and Muscle Disabilities.

THE TREATMENT OF GENITAL TUBERCULOSIS IN THE MALE *

WILLIAM C. QUINBY, M.D.
BOSTON

For the intelligent and therefore successful treatment of any surgical ailment an exact knowledge of its pathology and mode of invading the various structures of the body is most important. In the case of tuberculosis of the male genitalia such exact knowledge is in some respects lacking; especially in regard to the structures primarily attacked by this disease. At the present writing, the majority opinion holds that the first structure to become involved in the tuberculous process is the epididymis, and that from this the disease quickly spreads to involve the vesicle and prostate. A smaller number of investigators feel that the disease begins its genital invasion in the prostate, spreading from there to the vesicles and epididymis. This is a question which has long been argued, and is of much more than mere academic importance, because only by eradicating the primary focus may we expect the greatest number of cures.

In accordance with this majority opinion, that the tuberculous process begins in the epididymis, the operation of removal of this structure has been widely employed and in some instances has undoubtedly been followed by excellent results. By the operation, not only is the suppurating or tender focus in the scrotum disposed of, but also further disease either in the testis, or in the prostate and seminal vesicle may become quiescent. But that such a fortunate result cannot always be expected, and that our attempts to cure tuberculosis of the male genital tract by epididymectomy thus far leave much to be desired may be easily seen from the statistics collected by many surgeons. To mention two writers, Keyes[1] says, in speaking of tuberculosis of the testicle, "Relapse on the opposite side almost inevitably occurs." And from his table, it may be seen that, of fifty-three relapses in the other epididymis, forty-six had occurred within one year after operation on the side primarily diseased. Barney[2] says:

> It is a characteristic of the disease to attack the opposite epididymis in over one-half the cases, within a year or two of the time of involvement of the first side. This catastrophe occurs in spite of all efforts to prevent it, but early excision of the epididymis first attacked will improve the chances for the escape of its fellow.

Results such as these are hard to explain if we assume that the disease process is primary in the epididymis. On the other hand, they are easily explained if we consider the prostate and vesicles to be the point of first attack. If this assumption is made, it is evident that the focus nearer the center, untouched by the removal of the epididymis, is still present, ever ready to involve the second epididymis in the same manner as it did the first.

In what percentage of cases of tuberculosis of the epididymis are the prostate and vesicles free from this disease? It is evident that in the answer to this question lies the solution of our perplexity. The sources of evidence on which to base the answer thus far made use of are mainly two: necropsy findings, and clinical examination of the prostate and vesicles by digital exploration. Large series of postmortem statistics have been examined by various men, with the result that in an overwhelming majority of the cases the tuberculosis is found to involve the whole genital tract, at least on one side. Though a few isolated instances are recorded in which only the epididymis, the vesicle or the prostate was the seat of the disease, the number of such cases is far too small to be of weight in demonstrating the usual point of first attack. This can mean only that by the time the patient dies, the disease has progressed so far that its exact genital origin is obscure.

The clinical evidence that may be brought to bear on this question is even more insecure than is the postmortem, for it is admitted by nearly all clinicians that it is frequently impossible to detect the presence of tuberculosis in the prostate or vesicles, though the tuberculosis in the epididymis is obvious. On the other hand, Keyes makes the statement that every case of tuberculosis of the testis (epididymis) examined during ten years showed some involvement of the prostate.

For final conclusive evidence, it is therefore clear, I think, that we must turn to the "pathology of the living," that is, to the evidence obtained from histologic examination of tissue removed or investigated at operation. Though it may well be beyond the usual opportunity of any one of us to bring together an amount of such operative material adequate for the complete proof, nevertheless if the continued efforts of many working toward this end are made, we shall soon have our answer. It is, then, with the hope of stimulating a more general interest in this subject among urologists, rather than with the feeling that I am yet able to bring any final word on the subject, that I present this paper.

INVOLVEMENT OF OTHER ORGANS IN TUBERCULOSIS OF THE EPIDIDYMIS

As partial answer to the question, "In what percentage of cases of tuberculosis of the epididymis are the prostate and vesicles free from disease?" I am able to offer the histories of seven cases seen during the past two years at the Peter Bent Brigham Hospital. These patients have all been treated by complete removal of the whole of either one or both seminal tracts. The operation usually performed consisted of a unilateral vesiculectomy, vasectomy and epididymectomy; the operator using practically the same method which Dr. Young[3] has recently published. A small area of prostate was also removed when it could be demonstrated to be diseased.

Stated briefly, the answer which these cases bring to our question is that in *no* case were those structures central to the epididymis found free from tuberculosis, and that therefore the percentage is zero. Of course, I do not expect this result to obtain when a much larger accumulation of such operative evidence is available. It is interesting, nevertheless.

It is also of interest to note that, though I have been unable to find an epididymis which was tuberculous without there being at the same time a demonstrable tuberculosis of some more central portion of the genital tract, there has come under my observation a case of tuberculosis of the prostate in which the process was confined to this organ, or at least in which the epididymides showed no abnormality. The patient was operated on by prostatectomy, and has thus far shown no tuberculosis elsewhere in the genital tract. It is added to the cases herein reported, which may be briefly summarized here.

---

* From the Urological Clinic of the Peter Bent Brigham Hospital, Boston.

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

[1] Keyes: Tuberculosis of the Testicle; Observations on 100 patients, Ann. Surg., 1907, **45**, 918-937.

[2] Barney: Genital Tuberculosis, Mod. Urol., 1918, **1**, 498.

[3] Young, H. H.: Presentation of a Radical Operation for Tuberculosis of the Seminal Tract, Surg., Gynec. and Obst., 1918, **26**, 375.

The average age of the patients was 28, the oldest being 33 and the youngest 25. Four were single and three were married. The time from onset of evident disease in the epididymis till operation averaged about three months, with one exception in which the process was present for two years and nine months. In two cases both prostate and vesicle gave palpatory evidence of being diseased, while in three cases the vesicles only could be positively felt to be abnormal. In two cases the rectal examination was entirely negative. In three cases the urine contained pus; in four it was normal. In no case could evidence of renal or bladder tuberculosis be demonstrated. Five patients had a discharging sinus in the scrotum before presenting themselves for operation.

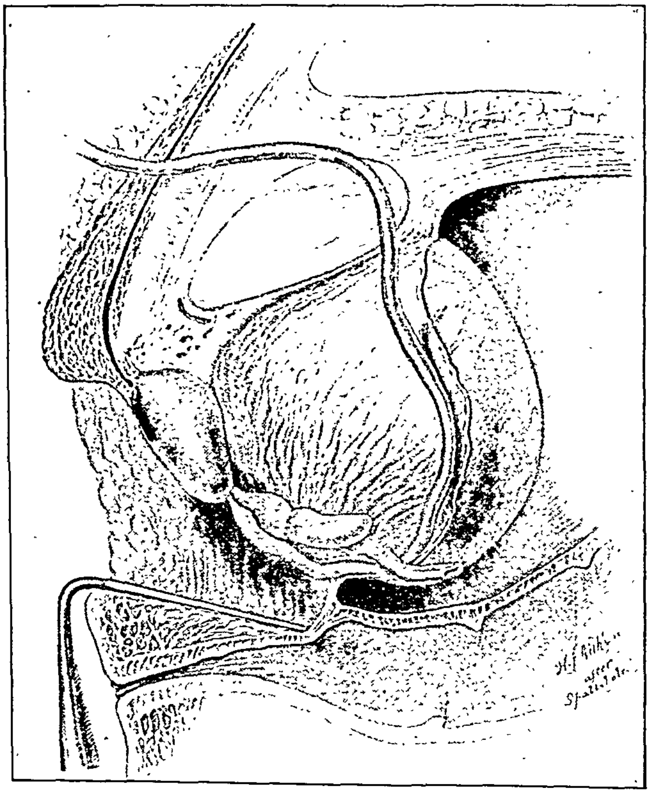

Fig. 1.—Sagittal section of male pelvis showing approach to vesicle by division of structures which unite the rectum and bulb of urethra. Note relation of ureter to vas and also pouch of peritoneum behind bladder.

CLINICAL RESULTS OF OPERATIONS

Each of these patients has been seen within the past month, six having reported personally at the hospital. One was seen by the nurse of the social service department. Only one patient has done badly and this poor result is clearly due to an error of surgical judgment in not removing the whole of a very evidently and extensively diseased vesicle. Two months after this operation, the other epididymis and testicle became extensively diseased and had to be removed. The patient is now well. With this exception, the history after operation in each of the remaining cases has been one of apparent return to complete health. In no other of them has there been any evidence of further extension of the tuberculosis. One patient underwent an acute infection by the gonococcus fifteen months after operation, and after four weeks of self-medication this resulted in an acute gonorrheal epididymitis of the side not operated on.

The average time since operation is thirteen months. This is not nearly so extensive a time as is necessary for conclusions in regard to recurrence of tuberculosis. I am sure that it is sufficient, however, to demonstrate that this more radical method of operation does not carry with it any unusual or unjustifiable complications or risks. I have not attempted the operation, however, in any case which showed signs of active tuberculosis elsewhere in the body.

CASES OF TUBERCULOSIS OF EPIDIDYMIS TREATED BY EXCISION OF ENTIRE SEMINAL TRACT

Case 1 (No. 5920).—*History.*—A student, aged 25, single, Dec. 18, 1916, complained of swelling and discharge from right testicle for four months. The family history and past history were both negative. There was no venereal disease. Four months previous to consultation, while working as a porter in a summer hotel, the patient had lifted a heavy piece of ice and noted pain in his right testicle. The pain had been followed by swelling, which had lasted from four to five days, at the end of which time the patient had seen a doctor. The doctor had aspirated it, obtaining a small amount of bloody fluid. The pain had then disappeared, but the swelling had remained, had increased slightly in size, and through the aspiration point, the patient had had a yellowish discharge. There were no night sweats, no cough, no urinary disturbance and no loss of weight.

Physical Examination.—Lungs were negative. Over the lower pole of the epididymis on the right was a small sinus discharging a thin, seropurulent material and here the skin was slightly puckered. The epididymis was considerably enlarged throughout but was not tender. The testicle appeared to be normal. The left testis and epididymis were not remarkable. The rectal examination was negative. The urine was normal.

Dec. 19, 1916, right vesiculectomy, vasectomy and epididymectomy were performed. The structures removed included an adjacent nodule in the prostate.

Jan. 4, 1917, the patient was discharged after a rather stormy convalescence. He had to be catheterized for several days, and the perineal wound oozed considerable bloody serum. The perineum had nearly healed on his leaving the hospital.

Pathologic Report.—The patient was suffering from tuberculosis of the epididymis, vas, seminal vesicle and prostate.

Subsequent History (outdoor department).—Jan. 12, 1917, the perineum was healed, and the scrotum nearly so. There was considerable induration in the right scrotum and cord but this was not tender. Erections had been present. There was no difficulty in regard to urination. The urine was clear, with a few granular shreds. It was passed at normal intervals.

Feb. 10, 1917, the patient had gained 8 pounds. The scrotal wound was not then entirely healed.

March 10, a sinus appeared in the perineum discharging a few drops of pus intermittently.

August 24, the sinus remained closed almost entirely. The patient had been working hard and had lost a few pounds of weight previously gained. He was put on a course of tuberculin.

October 1, during the summer vacation the patient showed marked improvement. There had been no further discharge from the sinus since the last note. He had gained about 15 pounds.

May 28, 1918, the patient reported that although he had been working hard during the past school year, his health had been excellent. Examination on this date proved both testes normal, the right being minus its epididymis. By rectal palpation, the prostate felt normal, but there was a small depressed area at its upper right side over which the rectal mucosa was puckered. The left vesicle could not be palpated. The expressed prostatic secretion was normal under the microscope and no pus was found. Spermatozoa were absent, however. The urine was normal in all respects.

Case 2 (No. 5880).—*History.*—Dec. 11, 1916, a laborer, aged 27, single, complained of swelling of the scrotum. The family history was negative. There was a rather vague history of pleurisy five year's previously and of gonorrhea eight years previously. The trouble began about six months before with pain in the groin and the scrotum. At this time an incision was made in the scrotum, which continued to discharge. A week previously the swelling and tenderness had increased. There were no urinary symptoms. The patient thought he had lost some weight but he did not know how much.

Physical Examination.—The lungs showed a slight increase of dulness with prolongation of expiration on the right at the apex. The roentgenogram was negative except for slight haziness in the region of the right apex. The left testis was three times its normal size on account of involvement of the whole epididymis. In the region of the lower pole, the skin was adherent about a sinus tract. The contents of the right scrotum were normal. The left cord was definitely thickened. By rectal palpation, no abnormality could be felt in the prostate. The left vesicle was definitely thickened, the right questionably so. The microscope showed that the urine contained a little pus and blood.

Dec. 13, 1916, vesiculectomy, vasectomy, epididymectomy and orchidectomy were performed on the left side. No evidence of prostatic involvement was to be seen. The right vesicle was normal, the left enlarged and adherent. Orchidectomy was done on account of an extensive necrosis of the testis.

December 23, the inguinal incision still discharged considerably and had become slightly infected. The perineal wound was nearly healed.

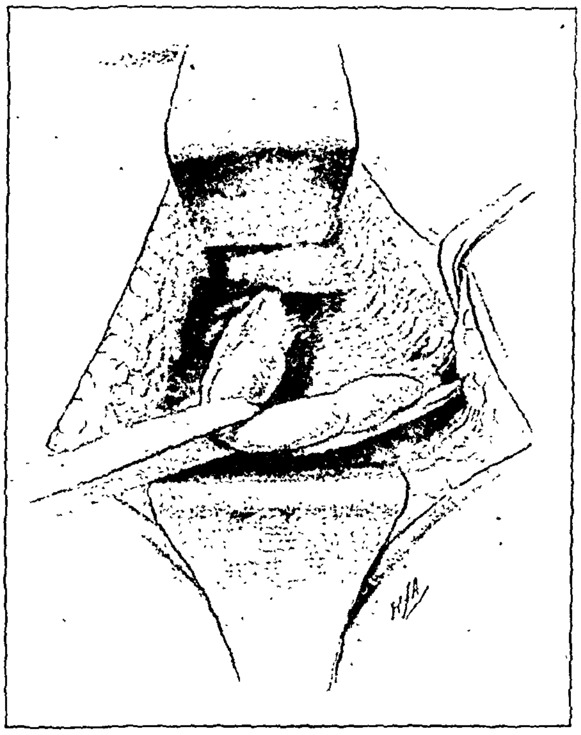

Fig. 2.—Method of traction on vas and vesicle after they have been separated from the base of the bladder.

Jan. 3, 1917, the inguinal wound was completely healed. The wounds in the lower part of the scrotum (area of original sinus) and the perineum still discharged a little. The urine was normal. The patient was sent to the outdoor department for dressings.

Pathologic Report.—He was suffering from tuberculosis of the testis, epididymis and seminal vesicle. The patient continued to have dressings for the slowly healing sinus in the outdoor department till Sept. 13, 1917. His general condition was excellent.

Subsequent History.—March 19, 1918, he reentered as No. 8392. Almost two months later he had acute urethritis five days after exposure. He used self medication in part and had a swelling and tenderness of right epididymis. Gonococci were found in the urethral discharge. His fever rose as high as 103 F. No tenderness was discovered by rectal palpation.

March 29, 1918, the process had run the usual course of a gonorrheal epididymitis. There was then much less soreness and swelling and the urethritis was only moderately severe. No evidence of recurrent tuberculosis had been seen. The patient was discharged to the outdoor department.

May 1, 1918, he was still under treatment for prostatitis. The epididymis was practically normal, except for an occasional small nodule. The urine was clear, without shreds.

Case 3 (No. 6017).—*History.*—Jan. 4, 1917, a butcher, aged 28, married, complained of swelling and slight pain in the left testicle. The family history was negative. He had had gonorrhea nine years before. He had not lost weight. He had been married seven years, and six years previously had had a child. Three and one-half months before consultation, the patient fell, striking the lower part of his back. A week later the testis began to swell and grow painful. For two weeks it had grown worse and had remained of the same size since. Walking was painful, though somewhat helped by a suspensory. There were no urinary symptoms.

Physical Examination.—The lungs and the right genitalia were normal. The left scrotum was twice the size of the right. The upper pole of the epididymis was nodular and hard, and the rest of the epididymis was definitely thickened. The cord was somewhat thickened. The skin was not adherent. By rectal palpation it was found that the left vesicle had one nodule near its top which could not be expressed, otherwise the rectal examination was negative. The urine was normal.

Jan. 6, 1917, left vesiculectomy, vasectomy and epididymectomy were performed. The vesicle was only slightly adherent. One small nodule in the prostate at the entrance of the ejaculatory duct was excised.

Jan. 9, 1917, the wounds were clean and healing well.

January 14, the patient was discharged after an uninterrupted convalescence.

Pathologic Report.—The patient had tuberculosis of the prostate, the seminal vesicle and epididymis.

Subsequent History.—Jan. 23, 1917, the wounds were solid. There was an entire absence of tenderness by rectal palpation. The rectal mucosa was more thick and velvety than usual over the prostate. The remaining vesicle was not palpable. The patient soon gained in weight. He was put through a course of antituberculous hygienic treatment.

May 27, 1918, the patient came to report. His health had been excellent since the operation. He had gained 4 or 5 pounds. He had coitus normally three or four times a week, but his wife had not borne a child since the one of six years ago. Both testes were rather small and somewhat atrophic. The left one, except for the absence of the epididymis, was the same as the right. The rectal examination was normal except for a few small adhesions of mucosa to the underlying structures. There were no urinary symptoms. It was impossible to obtain prostatic secretion by expression for examination. The urine was normal.

Case 4 (No. 6698).—*History.*—May 7, 1917, a storekeeper, aged 30, single, complained of a swelling of the testicle. The family history was negative. He had not had gonorrhea.

March 5, 1917, he had observed on walking that the left testis was swollen, tender and painful. He had stayed at home five days on account of the pain. The swelling had gradually decreased, but had not disappeared. Ten days previous to consultation, he had observed a soft area at the lower part of the scrotum which had broken and discharged pus a day before. There were no urinary symptoms. During the previous six months he had lost 8 pounds.

Physical Examination.—The lungs were normal. The left testis was slightly enlarged. The epididymis was swollen hard and nodular in both the upper and lower poles, and the lower part of the swelling had become adherent to skin about a fistulous tract. The cord was not thickened. The contents of the right scrotum were normal. No involvement of the prostate or testicles could be palpated. The urine was normal.

May 8, 1917, vesiculectomy, vasectomy and epididymectomy were performed on the left side. The left vesicle was found very rudimentary and evidently not diseased. No diseased areas of the prostate could be palpated. The ampulla of the vas was somewhat thickened.

May 20, 1917, the patient had made an absolutely uninterrupted convalescence and was discharged to the outdoor department for dressing of a small sinus in the scrotum.

Pathologic Report.—The patient had tuberculosis of the ampulla of the vas deferens and of the epididymis.

Subsequent History.—May 24, 1917, in the outdoor department, a stitch, which was causing slight discharge from the scrotum, was removed. A dry dressing was used.

June 6, 1918, he was seen by the nurse of the social service department. He had been entirely well since the previous visit.

Case 5 (No. 7266).—*History.*—Aug. 24, 1917, a sailor, aged 26, single, complained of deformed testes. The family history and past history were negative. There was no evidence of tuberculosis.

In May, 1914, he hurt his testicles in jumping a fence, and two days later passed bloody urine, with no pain, however. The condition lasted three weeks and stopped suddenly. The patient did not stop work. The left testis was at first swollen, then gradually diminished to the size of a robin's egg. He was then well till September, 1914, when the right testis became sore and swollen at the lower end. The swelling persisted but the pain disappeared.

August, 1917, the left side, which had been small since May, 1914, began to swell again in the lower pole, and to be painful. There were no urinary symptoms.

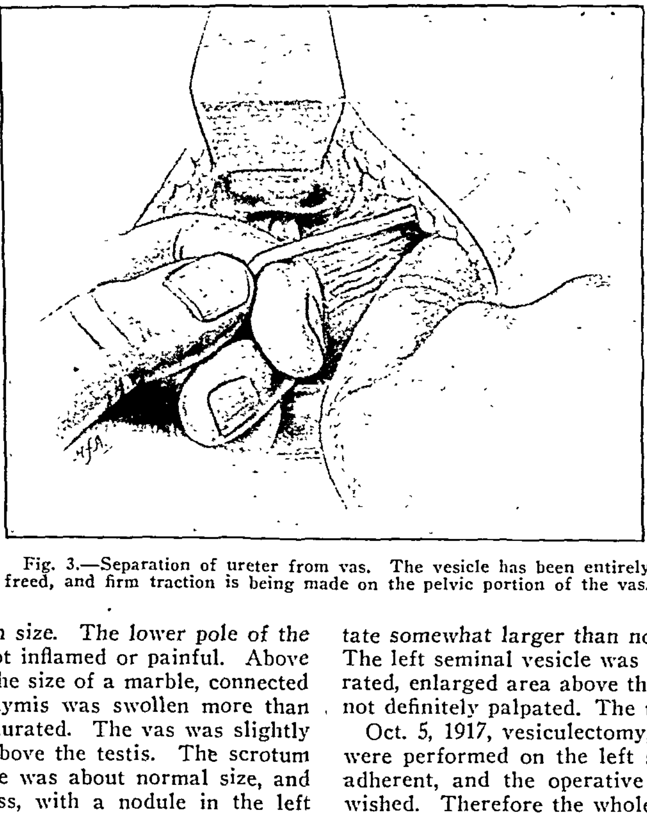

Fig. 3.—Separation of ureter from vas. The vesicle has been entirely freed, and firm traction is being made on the pelvic portion of the vas.

Physical Examination.—The lungs were negative. The right testis was about normal in size. The lower pole of the epididymis was enlarged, but not inflamed or painful. Above the testis was a discrete mass, the size of a marble, connected with the cord. The left epididymis was swollen more than the right and more diffusely indurated. The vas was slightly enlarged for a short distance above the testis. The scrotum was not involved. The prostate was about normal size, and of somewhat increased hardness, with a nodule in the left lobe. There was no pain on pressure. The seminal vesicles felt as nodular masses rising above the prostate, the left one being somewhat more marked than the right. The urine contained a few pus cells, as the microscope showed.

Aug. 27, 1917, double vesiculectomy, vasectomy and epididymectomy were performed. The left vesicle was more recently inflamed than the right, which was fibrous. No definite nodules were to be found in the prostate.

August 30, all drains were removed. The patient was free from pains and his general condition was good.

September 7, all wounds were healed.

September 12, he was discharged in good general condition. The scars were perfectly healed. The testes were slightly indurated, but were not at all painful. There was no ecchymosis. The urine still contained a little pus.

Pathologic Report.—The patient was suffering from tuberculosis of both epididymides and seminal vesicles. The vasa showed no change. A pig inoculated with the urine, Aug. 28, 1917, and killed Sept. 26, 1917, showed no sign of tuberculosis. The disease affected the left side for two years and nine months, and the right side for two years and seven months.

June 3, 1918, he was at work and in splendid health. He had gained from 15 to 18 pounds. Coitus was normal, but not as frequent as before. The testes were of normal size and freely movable in the scrotum. The cords were not thickened. By rectal palpation the prostate felt normal. At its upper limit, there was a definite shelf left by the removal of vesicles. The rectal mucosa was somewhat adherent. The urine was clear and acid, with a specific gravity of 1.014, and with no albumin and no sugar.

Case 6 (No. 6468).—Oct. 3, 1917, a barber, aged 33, married, complained of swelling and abscess on the left side of the scrotum.

History.—The family history was negative. The patient had been married twelve years and had eight children. He had had chancroid at 17 years of age and gonorrhea at 18. He had experienced no urinary troubles since. For the previous five months he had noticed that the urine had not been as clear as usual. He had observed swelling and pain in the left testicle about twelve weeks previous to consultation. There was no history of infection or trauma to account for the condition. The pain was of a dull aching character, relieved considerably by warm applications and a suspensory. A week later the patient felt perfectly well. The pain recurred in two weeks and the swelling, which persisted to date of consultation, finally led to an abscess which was later incised. He lost 10 pounds in two weeks.

Physical Examination.—The patient was a pale, poorly nourished Jew. The lungs appeared to be normal. The left scrotum was distinctly larger than the right, because of a large firm testicle and epididymis. The skin of the scrotum was adherent at the globus minor in the area of the previous incision. The cord seemed normal. The structures of the right scrotum were normal. Rectal examination showed a prostate somewhat larger than normal, but not tender or nodular. The left seminal vesicle was readily palpated as a hard, indurated, enlarged area above the prostate. The right vesicle was not definitely palpated. The urine contained considerable pus.

Oct. 5, 1917, vesiculectomy, vasectomy and epididymectomy were performed on the left side. The vesicle was markedly adherent, and the operative exposure not all that could be wished. Therefore the whole of the vesicle was not removed. As will be seen later, this was a definite error of surgical judgment.

Pathologic Report.—The patient had tuberculosis of the epididymis, vas and vesicle.

Subsequent History.—He made rather a slow convalescence. For several days he had an obstinate, moist, bronchial cough. The temperature was 102 F. on the sixth day. This ceased and the temperature became normal. The wounds healed slowly, especially that in the perineum which was still discharging a very little at his departure from the hospital, Nov. 2, 1917.

Dec. 4, 1917, it was found that though advised as to hygiene, diet, etc., the patient had been taking no care of himself at all. He had been working for the previous three days and had felt pretty well. The sinuses had not healed, however, and the day before the right testicle had become swollen and tender. There was a slight frequency of urination with slight terminal pain. There were no chills or cough. On examination, the right epididymis was slightly enlarged, but not nodular or fluctuant. Throughout the whole palpable course of the vas, there was extreme tenderness.

Dec. 14, 1917, he reentered the hospital as No. 7856. The process in the right scrotum had rapidly increased. The swelling was the size of a large lemon and the testicle and epididymis could not be differentiated. Rectal examination did not reveal any further involvement in the region of the prostate, but on the left side there was a boggy induration in the region where a portion of the vesicle was allowed to remain, and this was probably related to the persisting perineal sinus.

December 19, right orchidectomy was done. The testicle was found extensively involved by disease, and so removed, together with the epididymis and as much of the vas as could be secured by drawing it down from above.

December 23, a residual abscess appeared at the level of the internal inguinal ring on the right side. This was opened under cocain.

Jan. 24, 1918, the patient made a poor convalescence. He had hectic fever, especially at night, and did not react to forced feeding and antituberculous hygiene. The sinuses were treated with bismuth iodoform petrolatum paste.

Feb. 1, 1918, he was discharged though the sinuses still persisted.

June 5, 1918, he came to report that he was in a surprisingly good condition, having gained 10 pounds since leaving hospital. He spent the summer at the seashore and worked one day only each week. There was a minute sinus in the right groin and one in the right side of the perineum, but these discharged so little that no dressing was needed. The urine contained a little pus by microscopic examination. Coitus was normal but there was no ejaculated fluid.

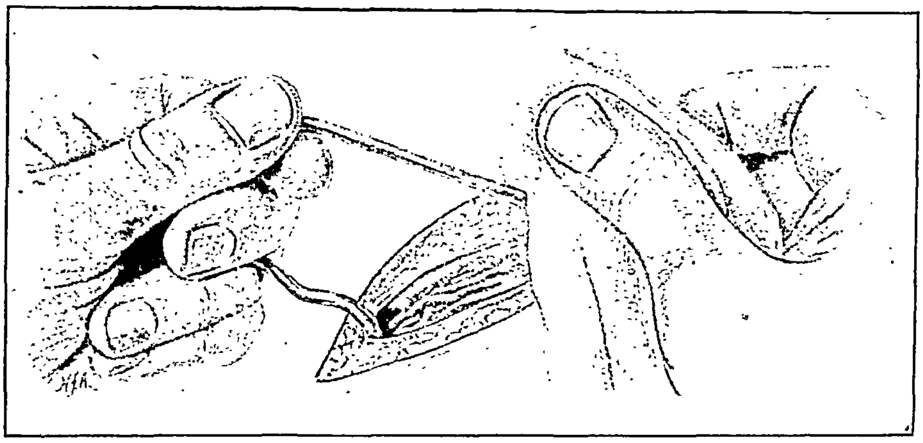

Fig. 4.—Inguinal incision. The spermatic cord from which the vas has been separated shows in the bottom of the wound. Traction is made on the vas, and at the same time the surrounding structures, together with the peritoneum, are wiped back by a gauze sponge.

Case 7 (No. 8326).—*History.*—March 7, 1918, a riveter, aged 26, married, complained of a swollen testicle. His mother had died of tuberculosis. He had been married three years and had one child 22 months old, who was well. He had had no cough or night sweats. He had lost 20 pounds in the previous two months. Six weeks before consultation, he had felt a dull pain in the scrotum. A week later he had experienced a swelling and tenderness in the left side of the scrotum, had felt poorly and could not work. He had stayed in bed and used poultices for the swelling which began to suppurate the previous week. Since his illness he had urinated once during the night. There were no other urinary symptoms.

Physical Examination.—Tactile and vocal fremitus increased at right apex posteriorly. There was dulness on percussion down to the midscapular region. There were no râles. There was an extensive involvement of the left epididymis by a low grade suppurative process, which was undoubtedly tuberculosis. The epididymis was enlarged at least five times its normal size, and at its upper pole, as well as at the lower, the disease had involved the skin, which at the upper pole had broken down and formed two sinuses. The contents of the right scrotum were normal. There was evidently no thickening of the cord on the left. By rectal palpation, there was a nodular thickening in the region of the left vas. The prostate felt normal, as also did the region of the right vas. The urine was normal.

March 8, 1918, vesiculectomy, vasectomy and epididymectomy were performed on the left side. The prostate was evidently not involved. A rather excessive adhesion of the vesicle to its surroundings caused moderate hemorrhage, easily controlled, however.

March 14, all drains were removed. The patient was comfortable, but for two days after operation, he complained of gas pains.

March 18, the perineal wound was well healed, and the one in the scrotum was granulating.

March 22, the fourteenth day, he was discharged in good condition. He had been out of bed for five days. There had been no fever since the operation. The slight discharge of seropurulent material from the area in the scrotum that remained was to be dressed for the patient in the outdoor department.

Pathologic Report.—The disease was tuberculosis of the epididymis, the vas deferens, and of the vesicle.

Subsequent History.—June 3, 1918, the sinus in the scrotum was healing slowly. The patient had gained 9 pounds and was stronger though he had not yet worked. The urine was normal.

Case 8 (No. 5987).—*Tuberculosis of the prostate; normal epididymides.—History.*—Dec. 30, 1916, an ex-policeman and ex-woodcarver, aged 67, a widower, complained of difficulty in passing water. The family history was negative. The patient's health had always been excellent. He had had gonorrhea forty years ago, though he denied syphilis. For the previous eight years he had been having gradually increasing difficulty in starting the stream, together with some increased frequency. There was no hematuria. Two weeks previous to consultation after an excessive amount of alcohol he had great increase in frequency, urgency and dysuria. Three days before he had had retention and at time of consultation he had not been able to empty the bladder for twenty-four hours.

Physical Examination.—No evidence of tuberculosis was to be found. The lungs were clear. Systolic blood pressure was 148 and diastolic 88. The bladder was distended to within 2 cm. of the umbilicus. The report of the rectal examination was missing.

December 30, suprapubic drainage of the bladder was accomplished under local anesthesia. About 1,200 c.c. of urine were withdrawn. Exploration of the prostate revealed marked hypertrophy of the median lobe.

Jan. 5, 1917, the general condition was much better. Suprapubic prostatectomy under ether was performed. Three lobes were removed, the left being markedly enlarged as was also the median, while the right lobe was about normal in size. The line of cleavage was easily found for the lateral lobes. The median lobe was less discrete and had to be removed with scissors in part. There was but little bleeding.

Pathologic Report.—The patient had tuberculosis of the prostate with glandular hyperplasia and chronic prostatitis.

Subsequent History.—Jan. 12, 1917, he was in good condition, being out of bed.

January 16, there was no longer any leakage of urine from the wound.

January 19, he was discharged in good condition.

Jan. 25, 1917, he reported that he rose three times each night to urinate. The urine was turbid. The catheter found 20 c.c. residual. He was to have bladder lavage with silver nitrate each week.

May 3, 1917, he was in good condition. There was no residual urine. There was a slight right hydrocele; otherwise the testes were normal. He was much disappointed that since the operation he had lost potency.

May 27, 1918, he reported that he had been entirely well in regard to the urinary system since the preceding year. He complained only of dizziness and constipation. The dizziness was evidently due to arteriosclerosis. The urine still contains a few pus shreds. The testes were symptomless, and except for the slight hydrocele noted in the foregoing, they were normal.

PATHOLOGIC FINDINGS

An extensive and searching pathologic investigation of the material obtained from this series of cases has been planned, but because of the unfortunate exigencies of the times, has not yet been completed. I regret that this is the case, and will ask your indulgence till opportunity offers when such results will form the basis of a subsequent communication. From a superficial histologic examination of the material, my impression is that the tuberculosis in the prostate or vesicle calls forth a tissue reaction of the chronic inflammatory type, characterized later by a considerable amount of connective tissue formation, in which caseation and liquefaction necrosis are but little marked. In the epididymis, however, the process is much more commonly a destructive one, leading to early necrosis and suppuration. We have here a notable analogy to the condition characteristically found in the tonsil on the one hand, and the cervical lymph node on the other.

Is the tuberculosis of the prostate and vesicle as seen in this material an older process than that of the epididymis? I am strongly of the opinion that it is, although I cannot definitely say so at present, for reasons previously mentioned. Certainly the findings thus far made are consistent with this assumption.

SUMMARY

Since it has been demonstrated that seven cases bearing tuberculous epididymides had a central area of infection with this disease at the time of operation, may it not be that many of our bad results, after the removal of the epididymis, are due solely to a misconception of the mode of invasion? Pathologic and clinical evidence of the past has not been able to afford a sure knowledge of this subject. The evidence which the cases under discussion offer is at least consistent with the hypothesis that when the male genitalia are affected with tuberculosis, this occurs first in the prostate or vesicle, to extend later to the epididymis. After removal of the entire seminal tract on one or both sides, the results are at least as good as those following epididymectomy alone. My belief is that the future will show that they are much better.

ABSTRACT OF DISCUSSION

DR. J. DELLINGER BARNEY, Boston: I was very much interested in Dr. Quinby's paper. We have now about two hundred cases which have been followed from a few months to several years since operation. It seems to me that the evidence is overwhelming, that the primary focus is not in the prostate or seminal vesicle, but in the epididymis. My reasons for this view are simple. Why is it that when the epididymis is removed on one, or particlarly both sides, the process in the seminal vesicle or the prostate will quiet down? This has taken place in all but two or three of our cases. In these cases there was a continuance of the process, with rupture of an abscess sometimes into the perineum—once, I believe, into the rectum. But in all other cases the prostate and the seminal vesicles which were markedly indurated and clearly tuberculous before operation, subsequently quieted down, resulting in a clinical cure. Also the tuberculous bladders have quieted down symptomatically and cystoscopically. It seems to me that this in itself is almost a sufficient answer.

I had occasion two or three years ago to go over the entire literature of the subject, and found that primary tuberculosis of the seminal vesicle or of the prostate was excessively rare, whereas secondary invasion from the epididymis, was almost constant. I have been informed by competent pathologists that it is sometimes impossible to tell the age of a tuberculosis process by either the gross or microscopic appearances.

I have great respect for the operations which Dr. Quinby has performed; but it is my belief that it is impossible to remove tuberculosis by such an operation, because by the time the diagnosis can be made, the process has spread outside of these organs and the lymphatics are involved. I do not believe that his, or any technic, will enable us to clear it all out.

DR. J. P. O'NEIL, Chicago: I think we are all agreed that these cases of tuberculosis are primarily surgical; but I do not believe that we should stop there; it is essential to eradicate the primary focus as much so as in the treatment of tuberculosis. I have used mostly Koch's old tuberculin in dilutions of 1 to 10, 1 to 100, and 1 to 1,000; and as high as 1 to 100,000. In all of these cases I started in with tuberculin immediately after the operation, or as soon afterward as possible.

If possible I make the injection about 4 o'clock in the afternoon. About twenty-four to twenty-eight hours after the injection a temperature reaction appears with a local reaction at the area primarily involved. I have found that we may have no temperature reaction until 48 hours afterward. I have often seen it go as long as 72 hours afterwards before a temperature reaction appeared. I think the temperature reaction did not go above 99.6 F. I believe that when we get above 99.6 F. we get above the opsonic index which we are really trying out there.

Many of these cases usually show no temperature reaction at all for six or seven days afterward. They will have merely the general reaction. You must be careful about increasing the doses. You should give about the same doses for two or three weeks at a time if the temperature reaction does not go above that. Provided you have no reaction you can increase the dosage one drop. I give tuberculin usually seven or eight days apart. My aim is to bring them, if I can, up to the point where I give them pure tuberculin eventually, that is, one drop of pure tuberculin without getting a reaction. It takes possibly two years or more to reach that point; but the effect that I have seen is in the abatement of the symptoms more than anything else. You must see that their living conditions are as good as possible. Pure tuberculin, if it is legitimately used, should be used in every case, because general tuberculosis or kidney tuberculosis is an adjunct following the treatment.

DR. JAMES A. GARDNER, Buffalo: I should like to ask Dr. Quinby about the number of sinuses that he has after this operation. It appeals to me as a very clever one, but in our hands we have found that an operation on the vesicles was much like an operation on the kidney; that we usually had tubercular tracts in spite of all we could do. Within the last few years, a municipal sanatorium at Perrysburg near Buffalo, was opened where there was administered the Rollier or sun treatment. I think the practitioners in Buffalo did not think very much of it until it had been established two or three years, and then a number of so-called hopeless cases, not only urinary cases, but bone tubercular cases—which they were glad to get rid of—were sent out there. They give a program at the Buffalo Academy of Medicine one evening during the winter at which they exhibit a number of these cases, and also show photographs and moving pictures. We were shown a number of cases which we felt were practically hopeless that had improved wonderfully. We have felt since that if we can remove some of the foci and send them there to be treated that they clear up reasonably well. I should be glad to hear what Dr. Quinby has to say about end results.

Dr. Oswald S. Lowsley, New York: When I was in Cincinnati recently, a gentleman whose name I do not just remember now, called my attention to an article he had written on the effect of ether anesthesia on early tuberculosis lesions. In this article he called attention to the fact that in certain pulmonary conditions where in operations it had been necessary to employ ether anesthesia the patient had derived some benefit when the disease was not too far advanced. He quoted a number of cases to bear this out; and on my return home I gave two or three patients ether anesthesia in connection with cystoscopy which was painful, in order to determine the truth of his assertions about kidney tuberculosis. They did show some improvement of their tuberculosis lesion; they both gained slightly in weight, and improved as regard their other symptoms. They were both early cases. What I did to them had absolutely nothing to do with their treatment, it was simply a matter of investigation.

Dr. W. C. Quinby, Boston: I am thankful to Dr. Barney for making the very frank remarks that he has, because my point in presenting this paper was to bring this subject to your attention; recognizing very well, indeed, that our treatment is not yet a final one. It was far from my intention to try to do unnecessary operating. That is not justifiable, and if we can definitely know that the removal of the epididymis is sufficient, I will be the first person to agree. But Dr. Barney is not consistent. He said that of about 200 cases of tuberculous epididymides, in all but two or three instances the disease in the prostate and vesicles has quieted down after the removal of the epididymis, and that there has been no recurrence. If the results of epididymectomy only, are as good as this, then there is no earthly point in these operations which I have been doing. But this recently mentioned very small number of recurrences is not what Dr. Barney has gone on record in print as finding from his statistics; neither is it shown by the statistics of any other men. Therefore I maintain that he is not consistent.

When one begins to draw deductions from embryologic sources on which to base the physiologic function of an organ of the body, one is treading on very insecure ground indeed. To consider the testicle an excretory organ because in its embryology it takes origin near the kidney, is no more logical than to consider the suprarenal an excretory organ simply because it takes origin in the embryo near the kidney in the general region of the wolffian body. This is no proof at all; it is a theory merely, fabricated to explain the clinical situation. To my mind it explains nothing whatsoever.

In regard to the pathologic question as to how one can tell the age of a tuberculous process, I quite agree with Dr. Barney that it is a very difficult thing to do, and for this reason I have been unwilling as yet to make any definite statement in regard to the material which I have secured by operation. I have the opinion of three or four pathologists whom we all recognize as being men of ability that it will probably be possible to tell the age of the tuberculosis when one has the whole tract for examination. It was planned to make an extensive serial section study of all this material, but this has not yet been done, because my technician has gone to the war.

Dr. Barney makes the point that it is impossible to remove all the tuberculosis. I quite agree with him. I do not pretend to remove all the tuberculosis. The outcome of surgical tuberculosis is improved by the removal of a certain amount of tuberculous tissue to give the patients' bodily forces and powers of resistance a sufficient opportunity to combat what remains. I feel in regard to these genital cases that they are in no sense different from those bearing a tuberculosis of the bowel or of the cervical glands. The problem is the same in all of them. If the surgeon states that by operation he is removing all the tuberculosis in the patient's body he merely illustrates his ignorance of the pathology of the disease. I do not feel that this operation which I have done removes all the tuberculosis. I do feel that, if the statistics which we have in hand showing that about half the cases suffer recurrence after a simple epididymectomy are correct, this makes it evident that there has not been sufficient tuberculosis removed to give the patient a chance to overcome the disease. Therefore more of the disease should be attacked than is done by the performance of a simple epididymectomy.

I agree with Dr. O'Neil's remarks concerning tuberculin. All of my patients have been put on a strict antituberculous hygiene and this includes regular visits to the hospital. They are also looked after by the social service department and they are given "old tuberculin."

In regard to Dr. Gardner's question about sinuses in the perineum following operation, this is an important point, and is the strongest argument which has previously been advanced against the perineal operation in tuberculosis. There was only one occasion in which the perineal sinus discharged for as long as three months, and in no case was there enough discharge to amount to anything.

I have not had any experience in regard to the subject discussed by Dr. Lowsley. Almost invariably all my operative work in urinary or genital cases is done under nitrous oxid anesthesia.

Dr. J. Dellinger Barney: Will Dr. Quinby please state the point that he is in doubt about?

Dr. Quinby: I quoted what you had published in an article written about two years ago. You said "It is characteristic of the disease to attack the opposite epididymis in over one half the cases, within a year or two of the time of the involvement of the first side. This catastrophe occurs in spite of all efforts to prevent it, but an early excision of the epididymis first attacked will improve the chances of its fellow;" and this statement is in direct accord with the statement made by Dr. Keyes, Jr., several years before. You now tell of cases to the number of 200 or more which you have personal knowledge of, and in only two or three of these did the genital tuberculosis of the vesicle or prostate fail to quiet down after the epididymis was removed. It is evident that these statements are not consistent.

Dr. Barney: I see your point of view. I think that the situation is this, and it will answer Dr. Quinby's question and straighten out the matter. Recurrence or relapse occurs on the opposite side in about 50 per cent. of the cases. This we have considered to be due to involvement of the prostate and vesicles from the first epididymis, but after removal of the first epididymis the process in the prostate and seminal vesicle quiets down in about 50 per cent. In the other 50 per cent. the process in the prostate or seminal vesicle does not subside before involvement of the second epididymis takes place. We have divided the second vas at the time of the removal of the first epididymis, or have taken out a section in the hope of preventing a recurrence on the second side, and have found the latter measure very successful. Where sterility can be shown to exist, as it does in most instances of this nature, no harm is done. It is also true in the cases where both epididymides have been taken out, with two or three exceptions, that the prostate and the vesicle which were previously tuberculous have quieted down to the extent that they are clinically cured. In other words, unilateral epididymovasectomy will retard a tuberculous process in the prostate and seminal vesicle and prevent relapse on the opposite side in about half the cases; in the other half the second epididymis becomes involved in spite of the removal of its fellow. After bilateral epididymovasectomy either at one or two sittings the prostate and seminal vesicle become clinically cured. Does this remove the apparent inconsistency of my remarks?

Health and Economic Loss.—I cannot estimate the economic losses that occur daily or yearly because of inefficient health and unsuccessfully treated disease. Great economists have tried but their estimates can never even approximate the real loss. There are other losses of greater importance than the economic losses. They are world losses in intellectual output; losses in public service; losses in ideal, commercial, professional, educational and religious progress; and, greatest of all, losses in human happiness—which follow this worldwide careless waste of human health and human life.—T. A. Storey, M.D., Ph.D., on Physical Training.

SOME NEW INSTRUMENTS IN OPERATIVE CYSTOSCOPY *

BRANSFORD LEWIS, M.D.
ST. LOUIS

PROSTATIC INCISOR

The pathologic reality and the various serious consequences of the condition known as contracture of the vesical neck are now well established. Endeavors to overcome the obstructive effects of this condition have been made by numerous authors, among whom are the following: Bottini, by the galvanocautery blade introduced through the whole urethra; Chetwood, by the same method applied through a perineal incision; Young, by punching out a section of the constricting neck. And Bugee has used high-frequency fulguration with the ordinary insulated wire.

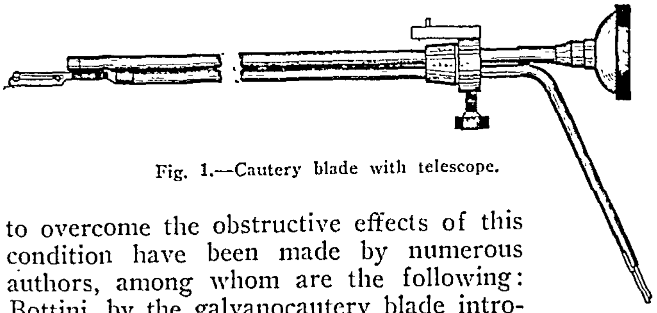

Fig. 1.—Cautery blade with telescope.

Two years ago or longer the desirability of opening the constricted channel without the perineal urethrotomy of Chetwood, or the strong tendency to hemorrhage induced by the punch operation of Young, was impressed on me. It was thought that some mode of applying fulguration more effectively than could be done by the wire was the desideratum. An iridoplatinum blade suggested itself.

With the assistance of the Wappler Electric Manufacturing Company and Mr. William A. Phillips, the instrument presented in Figure 1 has been evolved.

It consists of the blade mentioned, attached to a well-insulated wire, the center of a flexible shaft, capable of being attached by clips to either the direct or indirect telescope of my universal and operating cystoscope and utilized under direct observation of the operator.

The d'Arsonval (bipolar) current is used because of greater ease of control with respect to insulation, and the more effective cauterization it conveys.

A footswitch is used to turn on the current, when it is seen that the blade is properly applied against the constricting ring; and while the current is active the blade may be slowly drawn toward the operator, or back and forth, as desired.

Fig. 2.—Ureteral knife.

Pain is avoided by the use of one or two tablets of cocain through the urethral tablet depositor. Bleeding seldom accompanies, but if it does occur in connection with an inflamed prostatic urethra, the blood may be swept out of view by opening the irrigating cock of the cystoscope sheath.

The after-effects are so little in evidence that the cases are ambulatory with the exception, perhaps, of a day or so of quietude to avoid infection. Internal antiseptics (helmitol) are advisable coincidently.

As an illustration of the efficiency and at the same time the innocuousness of this method, the following notes are given in brief:

Case 1.—D. R., a farmer of Oswego, Kan., aged 64, was referred to Dr. E. E. Liggett. Fifteen years before, the patient had been hurt while riding horseback and had suffered from prostatitis and retention of urine. Six years later, he had had retention. Aug. 26, 1916, after an auto ride on a cold day, he had suffered from retention and had been catheterized every eight hours for several days. August 31, he consulted surgeons of another city, where, on account of the seriousness of the situation, continuous drainage through a catheter suprapubically was established. He was then sent home to be advised later as to when prostatectomy should be carried out. Dissatisfied with this arrangement, he consulted me in October. His condition was then bad. He was unable to pass any urine save through a catheter or the suprapubic drainage tube, and infection of the suprapubic opening was making itself manifest. The urine was of low specific gravity, indicating that the kidneys were beginning to participate in the degenerative process. Indeed, he was in no condition for prostatectomy, even if it had been desirable.

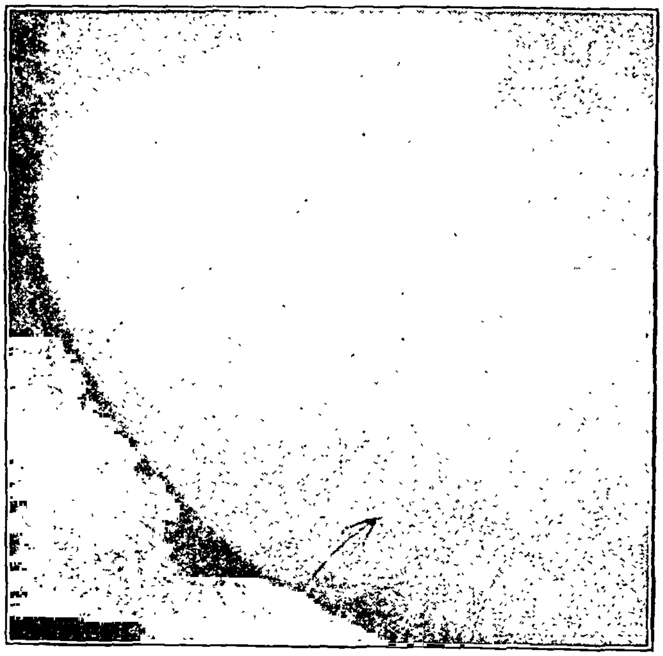

Fig. 3 (Case 2).—Shadow in contact with ureteral catheter, simulating ureteral stone (compare with Figure 4).

Fulguration with the prostatic incisor was first used October 17. The effects were striking. A few days after the first one, he was able to urinate voluntarily and to empty the bladder completely. The fulgurations were supplemented with deep urethral dilatings from time to time.

The patient has reported once or twice since, being in fine condition, with free urination and complete emptying of the bladder.

Several other instances of equally satisfactory results might be cited, but are omitted for lack of space.

URETERAL KNIFE

For a number of years, since about 1904, I have made use of ureteral scissors in connection with the operating cystoscope, for the purpose of opening a constricted ureter, or enlarging its orifice. In most such cases, they have given good service, but in some it was found that the lip of the orifice would slip

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

away from the closing blades of the scissors and an incomplete effect was the result.

The accompanying ureteral knife (Fig. 2), acting from behind forward, is intended to overcome this uncertainty. The blade is sunk and out of play while being introduced or until it is brought into play by turning the thumbscrew on the handle. The amount of divergence of the blade may be gaged and controlled by observing the number of turns of the screw and the direction of the blade as indicated by the little knob on the handle. It is obvious that the blade should be directed toward the superior lip of the orifice, so that the cutting will be toward the cavity of the bladder.

USE OF URETERAL FORCEPS FOR DIFFERENTIATION OF PHLEBOLITH FROM URETERAL STONE

Case 2.—Mrs. S., aged 42, was referred by Dr. Boynton of Sparta, Ill. She gave a history of intense suffering in the right renal region and also of intermittent colics on the left side, apparently low down in the ureter. A roentgenogram (Fig. 3) taken with a catheter in the ureter showed a shadow apparently in immediate contact with the catheter.

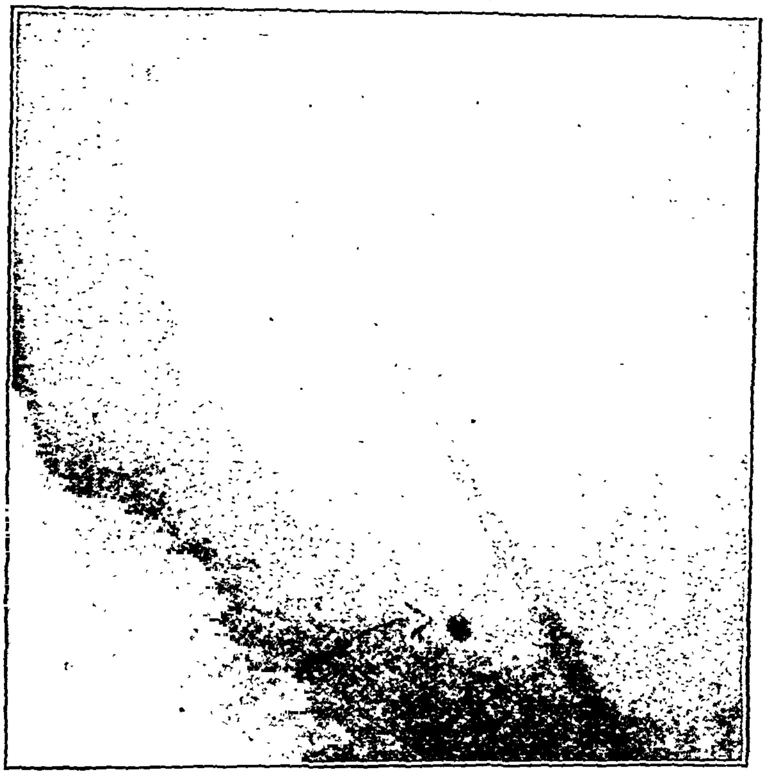

Fig. 4 (Case 2).—Ureteral forceps 3 inches up the ureter, removing the ureter from the shadow of a phlebolith previously in contact with a ureteral catheter (compare with Figure 3).

While the shape of the shadow did not conform to that typically characteristic of stone, it was not such as to make a definite denial of stone, and its *apparent apposition* to the catheter gave strong evidence presumptive of a stone, especially when taken in connection with the symptoms given. But this evidence was shown to be erroneous when ureteral forceps were introduced into the same ureter and another roentgenogram was taken (Fig. 4). The forceps, being more rigid than the catheter, straightened out the ureteral channel, *definitely separating* it from the shadow by a distance of half an inch. This action indicated that it could not be a stone within the ureter and therefore must be a phlebolith.

It is hoped that this sign may in certain cases prove as useful for differentiation as it proved in this one.

URETERAL DILATOR WITH PARALLEL DILATING BARS

The ureteral dilators previously submitted by me have had an objectionable feature in the fact that the most forcible dilatation was centered at some one point instead of being applied evenly along the ureter for a given distance (Figs. 5 and 6).

The latest model, herewith shown (Fig. 7), overcomes this objection and also gives a more forceful effect than the previous ones.

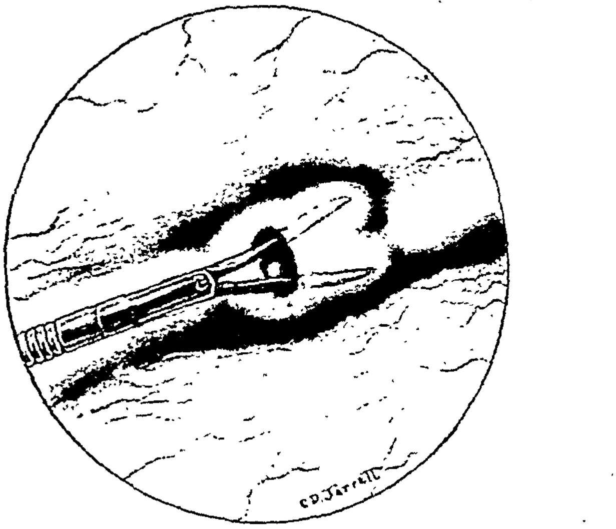

Fig. 5.—Ureteral dilator.

In addition to its use as a dilator, either at the meatus or above, it is conceivable that it might be used for traction on an incarcerated stone, as shown in Figure 8 *D*. I have not had an opportunity of using it in this way.

Since reading this paper, the author has removed an incarcerated stone by the method described above directly from the ureteral caliber, *fully 2 inches above the orifice.*

ABSTRACT OF DISCUSSION

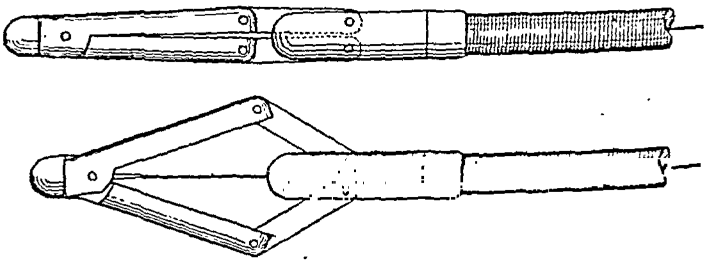

Fig. 6.—Ureteral dilator, closed and open.

Dr. William F. Braasch, Rochester, Minn: The instruments which Dr. Lewis demonstrated are a distinct improvement over his previous ones; the rectangular dilator is a great improvement over the *Kollmann dilator type.* The intraureteral knife ought to be much more practical than the scissors. Although the meatus may be cut with impunity, it is necessary to exercise great care in cutting the ureter itself. But in the upper portion of the ureter, above the distance of 2 c.c., I would be very loath to do much cutting. I have seen several ureters punctured by the introduction of stiff ureteral catheters. I was also much interested in Dr. Lewis' very ingenious method of distinguishing shadows in the para-ureteral area. I think it is a very valuable point, something well worth trying. The idea of using a stiff instrument which will not bend and will not permit the ureter to bend, or to straighten out the ureter drawing it away from the shadows, is a good point. I think it would be a good thing to follow in making a diagnosis of those troublesome shadows in the lower ureter. The unaided catheter is of comparatively little value in interpreting small shadows; it is as frequently misleading as it is of diagnostic value. I have long ago called attention to this point, and have advocated the use of the ureterogram. I can plainly see that even a stiff instrument or sound can also be misleading under certain conditions. I think that after all is said and done a final evidence as to the identity of these doubtful stones is the ureterogram. I have never yet seen a ureterogram fail if properly interpreted. I recognize the value of the method that Dr. Lewis has suggested in these particular cases.

DR. H. L. KRETSCHMER, Chicago: A contribution such as Dr. Lewis' is responsible, in part at least, for the fact that the entire treatment of stone in the ureter, for instance, has come back to the urologist, and that we have more cases referred to us for treatment for intravesical manipulation instead of having them operated on by the open method. Surely I believe that all of us, if we had a ureteral stone, would want to be operated on by the intravesical rather than by the open operation. Any improvement in the technic or in the instruments is always a step in the right direction. In reference to localizing shadows in the ureter, I think his method is very novel and very good; but it means that Dr. Lewis passed a shadowgraph catheter first, subjecting the patient to a second cystoscopic to accomplish his object. It required a second cystoscopy. Recently we have been doing that in another way. We make a double exposure with one plate. After the shadowgraph catheter has been passed an exposure is made. Then, without changing either the position of the patient or without changing the position of the plate, a second exposure is made on the same plate by changing the position of the tube. In cases of ureteral stone two shadowgraph catheters are seen and two ureteral calculi, both in exactly the same relationship to the catheter. In cases in which we suspect a stone, but the suspected stone shadow is produced by an extra ureteral shadow-producing body, we then obtain a double exposure, one of which shows a distinct interval between the suspicious shadow and the ureteral catheter. It seems to me in that way we can avoid two cystoscopic examinations.

FAMILIAL MACULAR DEGENERATION WITH AND WITHOUT DEMENTIA

WITH A REPORT OF TWO NEW CASES OF THE TYPE WITH DEMENTIA *

HOWARD S. CLARK, B.S., M.D.
Assistant Professor of Ophthalmology and Otolaryngology, University of Minnesota Medical School
MINNEAPOLIS

Since 1897, when R. D. Batten[1] reported two cases in brothers, each of whom showed symmetrical affections in the two eyes consisting of dark spots in the macula and pallor of the optic nerve heads, a small number of cases in families have been reported.

These cases belong in the classification of familial degenerative diseases, among which those affecting the eye are the amaurotic family idiocy of Tay and Sachs; the juvenile type of amaurotic family idiocy of Spielmeyer,[2] Vogt, F. E. Batten[3] and others, and familial macular degeneration with and without dementia.

Between Tay-Sachs' disease on the one hand and macular degeneration without dementia on the other there are, of course, great differences; but analysis of many cases of familial disease seems to show a gradual transition from one to the other. In fact, when one attempts to put together syndromes and to give them definite names, one is at once confronted by numbers of atypical cases that might belong to one of any two groups.

For example, the juvenile type of amaurotic family idiocy seems to merge on the one hand into the infantile type, and on the other into familial macular degeneration with dementia.

Of the form known as familial macular degeneration, we may say that, combined with symmetrical degeneration of the macular region of the two eyes, there is in some cases a cerebral degeneration causing dementia.

Oatman[4] divides this form of degenerative disease into two types: the macular type in which the retina alone is affected, and the maculocerebral type in which both retina and brain are attacked. In this discussion, when the term "macular type" is used, it refers to the type without dementia. The term "maculocerebral type" is used to convey the idea of the disease combined with dementia. In the macular type we have simply an affection of the eyes and no cerebral symptoms whatever. This begins during the period of puberty, between the ages of 12 and 14 years, though Stargardt[5] reports one case beginning as early as the eighth year. This is in marked distinction to the maculocerebral type, the form with dementia, which begins between the fifth and seventh years, the period of second dentition.

The condition in the two eyes is symmetrical, and the objective and subjective symptoms develop very gradually, though we find exceptions to this rule in Lutz[6] and Sterling.[7] The first symptom is diminution of central vision of both eyes and central scotoma for red and green, which goes on gradually until, after some years, there may be complete loss of central vision. The periphery of the field of vision is unaffected and shows normal boundaries. Because of disease of the macular region while the periphery of the retina remains fairly normal, the patient develops, first, excentric fixation, and finally, nystagmus.

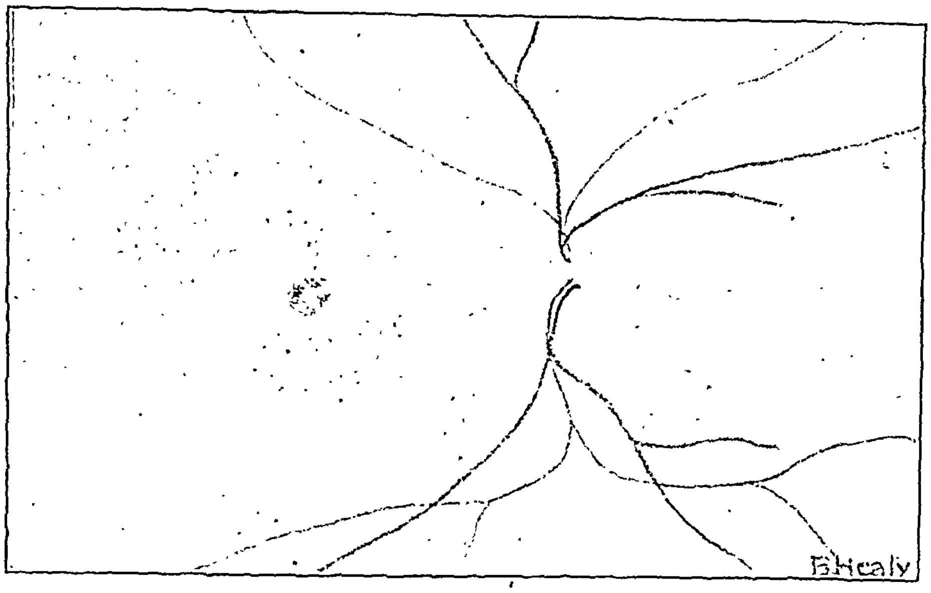

Fig. 1 (Case 1).—Right fundus, April, 1918. Left fundus practically the same. No optic nerve atrophy; vessels narrowed.

Ophthalmoscopically we find atrophy and degeneration of the retina almost always confined to the macular region, somewhat resembling the conditions produced by a senile macula. At first, the macular region shows delicate yellowish gray spots apparently not raised above the level of the surrounding fundus. These spots gradually coalesce and we have a dirty grayish yellow spot about the macula with a diameter equal to that of one or two disks. Covering the spot is a sprinkling of fine pigment granules. For a short distance around the grayish yellow spot the fundus may be dotted with a fine pigment, resembling black pepper. The retinal vessels are normal in the macular type. As to the general condition, we find in the macular type that there are no mental symptoms nor, in fact, any symptoms at all excepting failure of vision, excentric fixation and nystagmus. The general health is good in all reported cases.

This type is much more common than is the type combined with dementia. I was able to find reports of thirty-seven cases of the macular type and ten undoubted cases of the maculocerebral type. Of the latter, four additional cases have been reported which, however, we should class as atypical, because of some variations in history and symptoms.

The maculocerebral type, that is, the type which is characterized by the addition of cerebral symptoms, or dementia, to the eye symptoms already described, is distinguished from the macular type by the fact that the onset occurs at about the time of second dentition, instead of at puberty, and that cerebral changes begin at the same time as those in the macula. There is a gradual loss of intelligence leading to dementia. Ophthalmoscopically the changes are identical, except that optic nerve atrophy is more common in the type combined with dementia. The general health in practically all cases of both types reported has been remarkably good, and the patients have been well nourished, free from constitutional diseases and paralyses, and of good family history.

In addition to the cases that may be definitely designated as of the macular type and of maculocerebral type, we have some cases reported which, while conforming in many details to the accepted syndrome of the disease, present variations that prompt us to classify them as irregular cases. As examples, we have Stock's[8] three cases and Hirschberg's[9] one case.

REPORT OF TWO NEW CASES OF FAMILIAL MACULAR DEGENERATION WITH DEMENTIA

The patients in these cases are two of a family of five children. The other children of the family, one brother aged 7 years and two sisters aged 11 and 4, respectively, are in good health and are normal in every particular.

The two children who are affected present typical cases of the malculocerebral form, showing distinct cerebral symptoms as previously reported by F. E. Batten[10] and Oatman,[4] Nettleship,[11] and others.

The parents are persons of ordinary intelligence and in good health. There is no history of consanguinity, hereditary diseases, or mental diseases known in any branch of the family. There is no Jewish blood. The eyes of the parents are normal. There is no history of eye trouble in the grandparents or in the brothers or sisters of the parents or their descendants. The parents are farmers and give no history of venereal disease, and in both the Wassermann test was negative. In brief, there is absolutely nothing in the family history that has a bearing on this condition.

Case 1.—R. L., boy, aged 9 years, referred by Dr. C. L. Scofield, Benson, Minn., to Dr. J. P. Sedgwick, July 3, 1916, complained of poor vision and was of lowered intelligence.

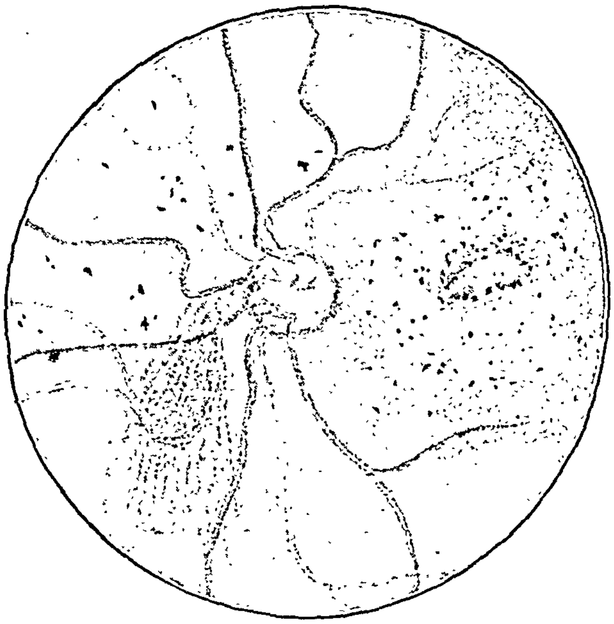

Fig. 2 (Case 2).—Left fundus, June, 1916. The retinal vessels two years later, have almost disappeared, reaching only slightly beyond the disk margin, and the optic nerve has become atrophic.

He was well nourished and strong, and showed no paralyses In earlier years he had been a normal child, as far as wa known, with apparently normal vision. He had played about a other children, had started school when about 6 years of age

and had learned the alphabet. At this time he had no difficulty with vision and was said to be mentally as alert as other children. Previous diseases were mild measles and whooping cough. After he had passed the age of 7 years, his vision began to fail and the parents noticed that he looked sidewise in order to see.

At the same time he had suffered a gradual loss of mental alertness, which had made him unable to continue in school. These symptoms had become gradually more marked until at the age of 9, he was quite dull mentally and had no central vision. He could see large objects with the periphery of the retina by turning the head—eccentric fixation. Horizontal ocular nystagmus was present to a moderate extent. Examination of the visual fields was found impossible because of the patient's limited intelligence, poor vision and nystagmus. The Wassermann reaction was negative, as was also the roentgenogram of the skull. The urine and the blood were negative. Externally, the eyes were normal, and the cornea and aqueous were clear. The iris was of normal appearance with no evidence of previous inflammation. The pupils were dilated and reacted little, if at all, to light, but did react to accommodation.

The ophthalmoscope showed that mediums were clear and the optic nerve and retinal vessels normal. At the macula was a horizontally oval spot resembling those in some cases of senile macula, about 1 D. in long diameter, of a dirty dark gray yellowish color, and with very fine pigment spots. The spot at the macula was quite distinctly marked off from the adjacent area, but the retina had a grayish cast for about 1 D. surrounding it. The remainder of the fundus was apparently normal. The appearance of the two eyes seemed almost identical. There were no edema, exudates, coarse pigment deposits nor any results of previous inflammation seen in the fundi. In March, 1918, nearly two years later, all conditions were practically unchanged.

Case 2.—P. L., girl, aged 13 years, a sister of the patient in Case 1, had always had good general health, though she had complained of headache. There were no paralyses. She was very well nourished and the urine, blood and Wassermann reaction were negative. The roentgenogram of the skull was negative. The only previous disease had been measles. Vision had fallen so that she could not go about alone. She had been a bright child and at about 6 years of age, had begun school, where she had learned to read and to write her name. She was about 7 years old and in the second grade when her vision and mind had begun to fail. One year after discontinuing school she had begun to have what her parents called "fits." Mentally, the child was demented until her intelligence was about that of an imbecile. Because of the nystagmus and mental condition, visual fields could not be taken. The pupils were dilated and reacted little, if at all, to light. She had eccentric fixation and the staring appearance of one almost blind.

Externally, the eyes showed no disease. Ophthalmoscopic examination showed clear media and no evidence of previous inflammation. The fundi showed a condition similar to that of the brother's, but seemingly more advanced. The optic nerve was distinctly atrophic and the retinal vessels were small. At the maculae was the same dirty grayish yellow area as seen in the brother's eyes. This area was about 1 D. in its horizontal diameter. Around this macular area, for a width of about 1½ D., the retina had an atrophic appearance, was of slightly lighter color than the rest of the fundus, and looked as though it had been sprinkled with fine black pepper. The fundi of the two eyes were alike, except that one showed in the nasal inferior quadrant some flat, pale, grayish splotches of pigment which were almost transparent, and which were traversed by the retinal vessels without modification.

In March, 1918, the condition was the same, except that considerable pigment deposits appeared in other parts of the fundi than the maculae, and the retinal vessels atrophied so that they extended only a short distance beyond the disk.

The two cases reported in the foregoing are of the type of familial macular degeneration with dementia, eight cases of which were reviewed. The eight do not include Hirschberg's one case or Stock's three, which may be classed as atypical.

Oatman[4] reported the cases of two children in a family of three, which are remarkably like the two new cases that I have just reported. The eldest and the youngest were affected with macular degeneration with dementia, while the intermediate child, aged 10, was normal in all respects.

Summarizing the findings in the cases of macular degeneration with dementia which are so far reported, we are able to form a definite syndrome. It is true that some cases vary in details, but this is true in summarizing the symptoms of any disease. Of this type we find reported five families, consisting of thirty-two persons, ten of whom were affected. In all the cases the two eyes were symmetrically affected.

The age at which patients were examined varies from 8 to 13 years, except in Nettleship's patient, who was 48 years old at the time of examination. The age of onset in the maculocerebral type varies from 5 to 7 years, approximately the period of second dentition. At this time, we have failure of vision and intellect, sometimes accompanied by headache and convulsions, though convulsions may not set in until later in the course of the disease, and have not always been reported present.

As stated before, judging by our knowledge of this condition at the present time, I am inclined to regard macular degeneration with and macular degeneration without dementia as the same disease. Why the onset of one type occurs at the time of the second dentition and is accompanied by cerebral degeneration, while the onset of the purely macular type occurs at puberty, and is not accompanied by cerebral change, remains to be explained.

Of the other type of the disease, that is, macular degeneration without dementia, I find thirty-seven undoubted cases. Stargardt[5] has reported to date ten cases in three families, which is the largest number reported by any observer.

ETIOLOGY

No positive statement of the cause of this disease can be made in the present state of our knowledge. There are no deformities, nor ocular anomalies reported, nor any chronic general disorders with which the disease can be brought into relation.

Syphilis is strikingly absent. Only Mayou,[12] in his family of three cases out of the ten reported cases of the type with dementia, mentions it as a possibility, and he simply states that "doubtful syphilitic history was given by the mother." Batten in three cases and Nettleship in one case ignore this point. Oatman, in his family of two cases, and the family of two new cases that I have reported, give definitely a history of the absence of syphilis.

We thus have four cases of the type with dementia reported with definite absence of syphilis, three in which syphilis is not mentioned and three with doubtful syphilitic history in the mother. Since it is very probable that syphilis would have been mentioned by Batten and Nettleship had it been present in their cases, we may assume that they did not find it. Concerning the incidence of syphilis in the type without dementia, of the thirty-four cases reported twenty-two are definitely nonsyphilitic. In ten cases the point is not mentioned, and in two cases of R. D. Batten syphilis is mentioned in the parents, but the children showed no signs of hereditary syphilis.

---

[12] Mayou, M. S.: Tr. Ophth. Soc. U. Kingdom, 1904, **24**, 142.

Thus out of forty-four reported cases in both types of the disease, twenty-six are reported definitely nonsyphilitic, the point is not mentioned in thirteen cases, and five cases give a doubtful syphilitic history. We should seem justified in excluding syphilis as an etiologic factor until such time as undoubted syphilis is demonstrated in a fair number of cases. At present the evidence is against it.

Against the theory that macular degeneration is congenital stands the fact that, in the type without dementia, vision remains good until the period from the tenth to the thirteenth year or about puberty, while in the type with dementia, the patient is normal until about the time of second dentition, at the age of 6 or 7 years.

In all analyzed cases, except Feingold's[13] three cases, the patients were Gentiles, in marked distinction to the Tay-Sachs type of amaurotic family idiocy, which attacks Jews almost exclusively.

Consanguinity cannot be totally excluded as an etiologic factor, as there was blood relationship in some reported cases, but those in which there was no blood relationship preponderate. As consanguinity has appeared, however, in four out of ten cases of the type with dementia, we must bear it in mind as a possible cause. In the cases of macular degeneration without dementia, it has appeared in only three out of thirty-four cases reported. Stargardt,[5] who in 1913 evidently had not seen the Jennings[14] report of 1909, describing three cases of the macular type in which the patients were children of first cousins, advances the theory that since consanguinity had not, to his knowledge, been reported in the macular type, it might possibly be a factor in determining whether the disease should assume the macular or maculocerebral type. His idea was that where there was consanguinity the form with dementia was more liable to appear than in those cases in which there was no blood relationship.

In the light of analysis of reported cases, I cannot at this time accept this theory, because I have reviewed cases enough of the type with dementia in which consanguinity is precluded to make the theory untenable. Besides, Jennings' three cases of the type without dementia in which there was consanguinity, make it even less probable that blood relation determines what form the disease shall assume.

Among forty-four cases of both types reported, seven cases give a definite history of consanguinity, twenty-two of no consanguinity, and in fourteen the point is not made clear. Thus, it may be seen that until we have an opportunity of analyzing many more carefully reported cases, the question of cansanguinity as an etiologic factor must remain unsettled. At present I may say that, while consanguinity may be a contributing factor, it is not a necessary element of the etiology.

Heredity must also be considered as a cause. Direct heredity, as in congenital cataract, etc., has not been observed. Rather this disease should be classed under collateral heredity, as defined by Bollinger, "when children of the same family suffer from the same disease, no cause for which can be found among parents or grandparents." No cases of the disease have been reported, except among brothers and sisters. We should bear heredity in mind as a possible etiologic factor, though the disease itself has not appeared in succeeding generations.

As to the nature of the disease, we are absolutely in the dark. Stargardt says, "The question of the nature of the inherited *Krankheitanlage* and of the direct cause of the disease process remains completely unsettled." He suggests that in the retinal disease, as also in the cerebral disease, which appears in the type with dementia, we have a certain autocytotoxin that has an affinity for the neuro-epithelium of the retina and, in some cases, for certain brain cells. He further suggests that when this purely hypothetic toxin attacks not only the retina, but also the brain cells, we have the type with dementia. Stock also assumes the presence of a toxin as a cause of his cases, which he reports under the name of *Familiäre amaurotische Demenz*.

Pusey[15] reports a family of five patients affected with the macular type, who showed arteriosclerosis of the terminal branches of the vessels in the macular region. He suggests that this arterial condition may have something to do with the macular disease.

Recorded cases reveal no previous illnesses that help us in regard to etiology. Only the common infectious diseases of childhood are mentioned.

The health and general condition of all patients of both types reported are strikingly good.

CHARACTERISTICS OF THE TWO TYPES

In the type with dementia the loss of vision and intelligence is gradual; no cases are reported in this type in which it has been rapid. The majority of cases have been examined from one to six years after onset, when mental and visual deterioration was well advanced. The vision of one of the patients whose case is reported in this paper was so poor six years after onset that she was practically blind. Two years after onset, her brother could see large objects fairly well. Of Mayou's patients, one examined four years after onset could count fingers. Mental deterioration seems to follow with about the same rapidity as that of vision. We may safely state that from three to six years is sufficient time in the maculocerebral type to change bright children with good vision to patients in a condition approaching amaurotic dementia.

In the type without dementia, in which the retina alone is involved, the loss of vision has been gradual, except in Lutz's[6] four cases and Stirling's[16] three cases, in which it was rapid at first. After the primary deterioration, the vision in this type may remain stationary for years and then fall again, but it does not go on to complete blindness.

In the two cases of the type without dementia in Batten's family, one child had "fits." One of the two patients whose cases I have reported (Patient 2) had convulsions, starting one year from the date of onset of the disease. One of Oatman's patients developed epileptiform seizures two years after the onset of the disease, which continued for a period of four years to the time of his last report, at which time they were less frequent. In the maculocerebral type of the disease, we find that convulsions are reported in four out of ten cases, and that they appeared from one to two years after the onset of the disease. Convulsions do not occur in the macular type of this disease, but only in the maculocerebral type.

[16] Stirling, A. W.: Ophthalmoscope, London, 1912, 10, 141.

No paralyses are reported in either type of macular degeneration. The eyes externally appear normal. There are no signs of inflammation and the refractive media are clear. In both types the reported cases showed eccentric fixation. There were also nystagmus and searching movements of the eyes.

The visual acuity depends on the stage of the disease at which the examination is made. It varies from slight deterioration to almost complete blindness, though the latter condition is more common in the maculocerebral type, in which the vision passes through all stages between these two extremes in from three to six years. The periphery of the fields is not contracted, and there is, at first, a central scotoma for red and green, and later an absolute central scotoma.

The macular region has been described in detail. As to the optic nerve, four out of ten cases of the type with dementia are reported as showing optic nerve atrophy, while in two cases there was paleness of the nerve. In the two cases that I have reported, one of the patients showed distinct optic nerve atrophy, while in the other case, the nerves were normal. Optic nerve atrophy is more commonly seen in the maculocerebral type than in the macular type. Outside the macular region, the fundus has been normal in a majority of reported cases, but enough atypical cases have been reported to make mention of these variations necessary. Examples of the latter may be found in Stargardt's[5] family S., which were of the type without dementia. The cases herein presented show some irregular pigmentation in other parts of the fundi.

DIFFERENTIATION

In the differentiation of familial macular degeneration with or without dementia, we have to consider amaurotic family idiocy and retinitis pigmentosa.

There are two types of amaurotic family idiocy: first, the typical cases (Tay-Sachs form) in which the onset occurs in infancy and, second, the so-called atypical cases in which the onset is delayed until childhood and which may be termed juvenile amaurotic idiocy.

Any attempt to construct a definite syndrome and to separate sharply the juvenile type of amaurotic family idiocy from maculocerebral degeneration lands the investigator in a wilderness of atypical cases, which is most disconcerting. The more cases he analyzes, the more is he convinced that the two types merge into one another in the same manner that the infantile and juvenile types of amaurotic family idiocy seem to merge. For example, Spielmeyer's[2] cases of juvenile type resembled maculocerebral degeneration with dementia in the matter of age of onset, course, mental and visual symptoms, and absence of paralyses.

Vogt's cases showed yet another juvenile type of amaurotic family idiocy, in which paralyses were present with loss of vision, which condition seems to link them, on the other hand, to the infantile type. The onset of Vogt's cases covered a period of from six to fourteen years; loss of vision led to complete blindness, and the paralyses to complete helplessness.

In discussing the cases of the juvenile type described by Spielmeyer and also those of Vogt, Jendrassik[17] says, "From the description, it is apparent that the two types stand in close relation and can hardly be classed as separate diseases. They are only members of the great family of heredodegenerations." He explains the intensity and rapidity with which the infantile type develops as depending on a lack of resistance due to the extreme youth of the patients.

I may briefly state that in differentiating the types of degenerations to which any particular cases may belong, one must consider the syndrome presented and then place the cases as nearly as possible where they belong after a thorough analysis of reported cases, bearing in mind the large percentage of atypical cases.

PATHOLOGY AND TREATMENT

Unfortunately, little is known of the pathologic conditions of macular degeneration with dementia. Stock's[8] report, while of atypical cases, should be mentioned. He holds that the process of the primary disease, so far as the eye is concerned, is destruction of rods and cones, and finally, gradual destruction of the neuro-epithelium and of the outer nuclear layer.

The subject of the treatment of this disease may be dismissed with the statement that, to date, there is no known remedy for the condition.

CONCLUSIONS

We have a large class of cases showing a great variety of motor, sensory and mental symptoms, which may be called heredodegenerations.

Those in which we are particularly interested as affecting the eyes, are retinitis pigmentosa, infantile amaurotic family idiocy, juvenile amaurotic family idiocy, and maculocerebral degeneration.

While what have come to be known as typical cases of these conditions are easily distinguishable one from another, there are many atypical cases which are transitional forms and might be in one of any two classes.

The cause of these degenerations is unknown. If there is a common cause, we are totally in the dark as to why the disease assumes one form at one time and a different one at another.

Pathologically in amaurotic family idiocy, the ganglion cells of the retina and central nervous system are attacked. From our slight present knowledge, I think that the retinal condition in maculocerebral degeneration is due to degeneration of the neuro-epithelium.

The relationship, if any, among these different types of degenerative disease must be cleared by a study of atypical cases.[18]

ABSTRACT OF DISCUSSION

Dr. Park Lewis, Buffalo: Two points are suggested in Dr. Clark's analysis of cases which apply equally to familial idiocy. The first is the fact that they are familial conditions, which would suggest heredity. But obviously they cannot be inherited conditions, because the children become degenerates before they reach the period in which they can propagate their kind. Perhaps, according to the mendelian system, this is what would be termed a unit character, and therein lies the possible explanation of the family relationship. The second point is that both these conditions occurred at critical periods in the life of the child, the first at the period of second dentition and the second at the period of adolescence. This fact suggests a relationship with other organic changes that are occurring at that time. The pineal gland and the thymus cease to function at this time. The ovaries, the testes and the pituitary begin to activate. Dr. Timme brought to my attention a most important fact connected with the glands of internal secretion. He has shown that the conditions which are perpetuated are not necessarily the individual conditions which appear in the child, but are due to a disparity in the relationship of the endocrine glands. That would be quite in accordance with the mendelian law.

Wolfsohn, J. M.: Amaurotic Idiocy, Arch. Int. Med., August, 1915, p. 257.

These people do not inherit a distinct unit character, but, in all probability, a tendency toward an imbalance in the endocrine system. That would explain how apparently normal parents can have children showing these degenerative characteristics. And it is not unlikely that if the family tree were followed we would find not only atrophies and neural degeneracies, but other conditions of which this neural degeneracy is simply one manifestation. The crux of the whole problem lies in the fact that optic atrophy is a common condition and that it is not infrequently associated with low mentality.

Dr. Harold Gifford, Omaha: These cases are not interesting until you have seen one or two of them. I have seen two of the Vogt type, which begin to show signs of defective vision and mentality at the age of the first dentition. In the Stargardt-Batten type, to which Dr. Clark refers, the patients develop macular degeneration at puberty, but not cerebral degeneration. In my experience those cases are the most common. Dr. Clark is right in laying down the proposition that it is impossible to draw a dividing line between the groups, and that the chances are that they all represent a series in which there is something defective in the nervous system. Or you may explain it by the exhaustion theory of Edinger, or it may be attributed to a defective "anlage." We do not know the reason why it is, but the fact remains that the retinal cells and the cerebral cells tend to degenerate at an early age. This Stargardt-Batten type is the one we must look for. These children live to the age of puberty, are perfectly normal, and then their vision begins to fade, and if you examine their retinas at this time you will find a little dusky pigmentation in the center of the macula. It looks as if there was a little soot spread over it and partly wiped off. This pigment then accumulates in larger clumps and you see little areas of whitish degeneration mixed with it. It extends out, perhaps, two disk breadths in diameter and then stops. The periphery remains normal, and they retain good mentality. Recently I saw cases with everything typical in the family, except that instead of beginning at the age of puberty, I am quite certain that their trouble began along about seven or eight years of age. In other words, the action of the sexual cells has nothing to do with it, and the fact that the Vogt type, which usually begins at the beginning of the second dentition, is also coincident with the time when the children have to use their eyes and their minds actively, may indicate that this is a mere coincidence. The child may be slightly defective, and it passes entirely unnoticed until the child goes to school, when it is found out that there is something wrong. This particular type goes on to idiocy or dementia and epileptiform convulsions, paralyses, etc.

To show how these types run into one another: A family is reported by Higien, in which one child had the typical Tay-Sachs degeneration, beginning in infancy, the child dying in a few years. The second child had the Vogt type, beginning with the second dentition and going on in the usual way; and the third had the Stargardt-Batten type. Dr. Brown Pusey has suggested that this Stargardt-Batten type of macular degeneration is nothing more or less than a familial tendency to arteriosclerosis of the central portion of the retina. I think that theory is worthy of consideration.

Dr. E. J. Bernstein, Detroit: I have had only one case of the Tay-Sachs type of amaurotic family idiocy. Looking up the etiology, I find that many men lay stress on consanguinity as a cause. That is simply a confession of ignorance. I cannot understand, in the face of the great number of married people who are related and who have perfectly healthy progeny, why consanguinity should be assigned as a cause of disease in the small number of cases in which some stigmata develop.

Amaurotic family idiocy usually occurs among Jewish children; marriage between relatives is very common among Jews, but no one accuses the Jews of degeneracy, as a rule. Very few of these cases usually occur among the Russian Jews. It seems to me that this form of degeneracy is due to the economic conditions under which the parents have lived for so many years and not to consanguinity.

PERICHOLECYSTITIC ADHESIONS

THEIR IMPORTANCE AND CLINICAL RECOGNITION *

FRANK SMITHIES, M.D.
Associate Professor of Medicine, University of Illinois, College of Medicine; Gastro-Enterologist, Augustana Hospital
CHICAGO

Experimentally by Rosenow,[1] pathologically by MacCarty[2] and clinically by Fowler,[3] Cheney[4] and myself,[5] it has been satisfactorily demonstrated that affections of the gallbladder commonly represent progressing infection of the structures forming the gallbladder wall. The infecting bacteria are usually blood-borne. In a large degree, abnormal contents of the gallbladder are the by-products resulting from bacterially induced inflammation involving any or all of the four layers of tissue comprising the wall of the viscus.

In origin, pericholecystitic adhesions may be intrinsic, that is, occurring as a consequence of changes primary in the gallbladder, or extrinsic, that is, secondary involvement of the gallbladder, due to disease in neighboring structures.

The term "pericholecystitic adhesions" commonly signifies the complications resulting from inflammatory processes arising in the gallbladder wall and involving the serous layer. The extrinsic origin of gallbladder adhesions is comparatively infrequent. Such lesions include primary and secondary malignancy involving the gallbladder, contiguous invasion of gallbladder structure from disease in adjacent viscera (most commonly, ulcerative processes of the duodenum, stomach, bile ducts or colon), or inflammatory or malignant disease originating in the peritoneum.

The newer laboratory and clinical studies have clearly proved that since gallbladder disease is commonly initiated by bacterial growth, the manifestations of the inflammatory reaction on the part of the gallbladder wall may be continuous and progressive (acutely or chronically) or intermittent at variously separated intervals. Pathologically, two facts are consequently emphasized: First, very extensive pericholecystitic adhesions may arise within a short time, should there be actively progressive bacterial invasion, or similar lesions may represent years of disease, should the infecting organisms be of low virulence, the tissue defense strong or the extension of infection intermittent. Second, the clinical or histopathologic study of pericholecystitic adhesions furnishes no clue as to the time duration of the existing evidences of inflammatory tissue reaction. These facts are further commented on later.

MATERIAL STUDIED

The cases furnishing the basis of this report have been studied during the past eight years. On account of space, this paper must be limited to a consideration of pericholecystitic adhesions arising from disease intrinsic in the gallbladder. It may, however, be mentioned here that of 556 operatively demonstrated instances of benign gastric ulcer, gallbladder adhesions were noted in 41, or 7.3 per cent.; of 1,291 cases of duodenal ulcer similarly studied, pericholecystitic adhesions were present in 149, or 11.5 per cent., and of 947 cases of gastric cancer proved operatively or at necropsy, the gallbladder was invaded in 51, or 5.4 per cent. It is thus apparent that lesions extrinsic to the gallbladder may be complicated by pericholecystitic adhesions quite frequently enough to render such complication important from the standpoint of diagnosis, prognosis and therapy.

PERICHOLECYSTITIC ADHESIONS IN DISEASE ARISING PRIMARILY IN THE GALLBLADDER

A year ago I placed on record[5] the pathologic and clinical manifestations of 1,000 surgically demonstrated instances of gallbladder disease. This material has been restudied with respect to pericholecystic adhesions. The facts resulting from this study are now presented.

Frequency.—Including twenty-one cases of primary malignancy of the gallbladder, there were pericholecystitic adhesions in 489 (48.9 per cent.) of the 1,000 cases of intrinsic gallbladder disease. In sixty-five cases of the adherent gallbladders the viscus was universally adherent, buried in dense adhesions, or the structures involved by adhesions were not definitely determined. This group of cases has been excluded from the study and analysis made of the remaining 424 cases in which adhesions extended from the gallbladder to neighboring tissues.

Viscera Involved by Pericholecystitic Adhesions.—Table 1 demonstrates how extensive may be the scope of such adhesions and furnishes significant information respecting the degree to which pericholecystitic adhesions may modify the clinical pictures of disease either of the gallbladder itself or of abdominal viscera, particularly such as are concerned with digestion and assimilation. Attention is called to the facts that, in nearly one of three cases of gallbladder disease, adhesions involve the bile ducts (cystic duct 24.5 per cent., common duct 5.4 per cent. and hepatic duct 1.4 per cent.); that in nearly one of four cases, pericholecystitic adhesions reach the duodenum, causing some anomaly in contour, position or function, and that in more than one of ten cases the gallbladder adhesions are attached to the stomach, commonly at or near the pylorus. Adhesions to the omentum, the colon and the liver are frequent enough to merit serious consideration, if from no other standpoint than that of prognosis, when it is recalled that such adhesions are not rarely infected and represent bridges of inflamed serosa by which bacteria may be transplanted to viscera far removed from the initial bacterial focus. That such conception is not unimportant is emphasized by noting that in this series, pericholecystitic adhesions involved the pancreas eight times, the appendix or cecum three times, and a cystic ovary once.

TABLE 1.—PERICHOLECYSTITIC ADHESIONS; TOTAL GALLBLADDERS ADHERENT IN 1,000 CASES OF GALLBLADDER DISEASE (INCLUDING MALIGNANT—21)

	No. of Times		Percentage
To adjacent structures	489	or	48.9
Adhesions universal and not specified	65	or	6.5
Structures involved by adhesions in	424	or	42.4

FREQUENCY OF INVOLVEMENT OF ADJACENT STRUCTURES

Structure		No. of Times		Percentage
Cystic duct		104	or	24.5
Duodenum	96	97	or	22.8
Ampulla of Vater	1			
Stomach: pylorus	38	44	or	10.4
Stomach: other part of	6			
Omentum		43	or	10.1
Colon—Hepatic flexure	35	38	or	8.9
Transverse	3			
Liver		30	or	7.7
Common duct		23	or	5.4
Pancreas		8	or	1.9
Hepatic duct		6	or	1.4
Anterior abdominal wall		6	or	1.4
Appendix and cecum		3	or	0.7
Ovarian cyst		1	or	0.24

Frequency of Pericholecystitic Adhesions Simultaneously Involving Two or More Structures.—Table 2 indicates that in eighty-four cases, or 19.5 per cent., in which the gallbladder was adherent, multiple visceral attachments were present. It will be observed that the duodenum, the pylorus, the colon and the bile ducts were most frequently the locations of such multiple adhesions. The occurrence of eleven cases of duodenal or pyloric peptic ulcer (13.3 per cent.) in connection with multiple pericholecystitic adhesions gives significant hints relative to the clinical problems in such cases.

TABLE 2.—FREQUENCY OF PERICHOLECYSTITIC ADHESIONS SIMULTANEOUSLY INVOLVING VARIOUS STRUCTURES

Duodenum and cystic duct	13
Ulcer, duodenum or pyloric	11
Duodenum and colon	9
Duodenum and pylorus	9
Duodenum and liver	7
Duodenum and omentum	6
Duodenum, pylorus and cystic duct	6
Cystic duct and colon	5
Cystic and common ducts	4
Pylorus, duodenum, liver and colon	4
Omentum and colon	2
Duodenum, colon and liver	2
Liver and stomach	2
Cystic and hepatic ducts	2
Cystic duct and anterior abdominal wall	2
Multiple structures involved in	84
Or 19.5 per cent.	
Stone cases adherent	165 or 38.9 per cent.
Nonstone cases adherent	259 or 61.1 per cent.

Gallbladder Contents.—In the cases in which pericholecystitic adhesions were demonstrated, the viscus contained calculi in 165 instances (38.9 per cent.). In 259 cases, or 61.1 per cent., no calculi were present. It would thus seem apparent that gallbladders free from stones are adherent to neighboring structures nearly twice as frequently as are those in which stones are found. A biopathologic explanation of this fact is evidently possible. It is quite likely that when adhesions form rapidly and extensively, there exists active, progressive infection which causes exuberant inflammatory reaction in the serous coat of the gallbladder or the lymph channels, before great damage is done to the gallbladder mucosa with consequent marked alteration in the gallbladder content or interference with the free emptying of the viscus.

The foregoing facts also emphasize the fact that in the absence of the commonly considered clinical history of gallstones, one is not justified in assuming that the gallbladder is not seriously at fault. It is quite apparent that not only may the gallbladder function be seriously interfered with, but that the viscus may be the abdominal focus of infection from which bacteria may be widely disseminated. Moreover, the presence and extension of such pericholecystitic adhesions may interfere with the proper working of the digestive apparatus more than would the existence of calculi in the gallbladder.

Pathologic Effects of Pericholecystitic Adhesions.—There were eighteen instances of perforation of the gallbladder with extensive pericholecystitic infected adhesions, in seven of which stones lay imbedded.

There were five instances of acute perforation in which the gallbladder was surrounded by extensive, recent adhesions and pus. In one case, a pericholecystitic abscess appeared to originate from an adjacent, enlarged and infected lymph node. In seven cases, adhesions from the gallbladder to the duodenal or pyloric ulcer cemented the viscera together and was the site of protected perforation with resultant deformity and malposition of the parts. There were four instances of fistula between the gallbladder and the duodenum or stomach (duodenum three, and pylorus one). Two cases of fistula between the gallbladder and the hepatic portion of the colon were observed. A gallbladder appendix fistula was noted once. In another case, a stone had worked its way from an adherent gallbladder into the head of the pancreas.

Most commonly, the gross effects of pericholecystitic adhesions was to interfere with the free emptying of the viscus. This was particularly frequent in that great group of adhesions involving the cystic or the common duct (29.9 per cent.). In such cases, the gallbladder was often so tightly bound down that sharp angulation of the ducts resulted and enormous dilatation of the viscus followed. Not rarely the gallbladder contents measured more than a liter. The ducts themselves, proximal to the adhesions, were frequently dilated almost to the diameter of one's thumb. Such embarrassment to the free emptying of the gallbladder repeatedly accounted for the major clinical symptoms and signs pointing to gallbladder malfunction. Separation of such pericholecystitic adhesions not uncommonly permitted the free emptying of the gallbladder and the subsidence of signs of obstructed bile flow. In nine cases in which the bile ducts were involved by stenosing adhesions, enlargement of the liver of a cirrhosis-like type was recorded.

Pericholecystitic adhesions to the duodenum were sufficiently pronounced to cause malformation, some degree of stenosis, fixation, or faulty position in 43, or 44.3 per cent., of the ninety-seven instances in which such adhesions included that portion of the intestine. The adhesions were commonly attached to the second and third portions of the duodenum. In only nineteen cases was the first portion of the duodenum extensively involved. This fact is significant diagnostically when it is recalled that the first portion of the duodenum is the common location of peptic ulcer. Only once did pericholecystitic adhesion extend distally as far as the papilla of Vater. There were seven instances in which strong adhesive bands resulted in sharp constriction and angulation of the duodenum and in which, proximal to such constricting bands, the intestine was greatly dilated and exhibited intense vascular engorgement.

Malposition of the duodenum was sometimes extreme, the viscus often being drawn up beneath the liver and firmly fixed there. In ten cases of this type there was cicatricial stenosis of the intestine.

Pericholecystitic adhesions involving the pylorus or other parts of the stomach caused obstruction to free gastric emptying in twenty-three, or 54.5 per cent., of the forty-four cases in which such adhesions existed. In thirteen cases there was definite pyloric stenosis, seven of these being due to malignant adhesions. Deformity of pyloric contour was present in twenty-nine cases. Abnormal position of the pylorus, genernally partial or complete fixation to the right of the midline (even direct attachment to the liver), was observed in twelve cases where pericholecystitic adhesions involved the stomach.

Gross deformity of the colon was recorded in nine (26 per cent.) of the thirty-eight cases where adhesions reached the colon. Three of these cases were malignant. In the remaining six cases the colon was pulled up beneath the liver, tied to the gallbladder, the duodenum or the anterior abdominal wall. There were two instances in which strong nonmalignant adhesions between the gallbladder and the hepatic flexure of the colon caused sufficient obstruction to lead to the laparotomy at which gallbladder disease was demonstrated to be responsible for the colon stenosis.

CLINICAL MANIFESTATION OF PERICHOLECYSTITIC ADHESIONS

It should be stated here that in eighteen cases, or 4.2 per cent., there were no prelaparotomy symptoms or signs pointing to abnormality of the gallbladder or the digestive apparatus. The operative procedure was instituted for the relief of other disorders and at the abdominal exploration, the gallbladder pathology was demonstrated.

Of the remaining 406 cases, malignancy was present in twenty-one, and although such malignant disease was not always suspected to involve the gall tract, before laparotomy, neoplasms were considered probable in the clinical diagnosis. There thus remain 385 cases of pericholecystitic adhesions in which clinically the preoperative departures from normal were sufficiently pronounced to warrant exploration of the right upper abdominal quadrant. These clinical symptoms and signs can be considered only very briefly.

Symptoms.—It is quite impossible to differentiate dyspeptic disturbances due to gallbladder disease without pericholecystitic adhesions from such disease complicated by adhesions, unless there is clinical evidence of gross abnormality in function in adjacent viscera coexistent with the gallbladder upset. Such abnormal function is commonly of a mechanical type, as for example, when there is stenosis of ducts, the stomach, duodenum or colon, is in the nature of such acute right upper abdominal crisis as occurs in gallbladder or ulcer perforation with abscess. In cases with clinical courses of this form, in the absence of proof of the existence of primary disease in the stomach, duodenum or colon and in the presence of dyspepsia of the gallbladder type, one may suspect that symptoms and signs that experience has proved to be unusual in ordinary uncomplicated gallbladder ailments are produced by pericholecystic adhesions. Special examinations and laparotomy may eventually substantiate this suspicion.

1. Pain. Apart from the pain due to ulcer or malignancy involving the stomach or duodenum, when there exists coincident gallbladder disease, two main sources of pain due to the gallbladder disturbance are possible: first, pain due to the passage of calculi and that due to adhesions interfering with free emptying of the gallbladder. In both types of lesion "colics" may be severe. They were present in rather more than 60 per cent. of our stone cases and nearly 55 per cent. of the nonstone cases, in which pericholecystitic adhesions interfered with free emptying of the gallbladder and ducts. It is thus evident that there is little in the clinical history of pain that permits segregation of the gallstone cases from those in which gallbladders are the origin of adhesions to neighboring structures.

When colicky attacks of pain are not recorded, the manifestations of right upper quadrant may be exceedingly indefinite. A sensation of distention, fulness, up-pressure, or crowding may be annoying. The distress is commonly most pronounced soon after taking food or during the night. The former distress appears to arise as a consequence of an embarrassed gallbladder attempting to empty its contents when food begins to leave the stomach. The latter type of discomfort seems to result from the fact that the distended, inflamed gallbladder is irritated by gastric hunger contractions and a fecal or gas-filled hepatic colon crowding up into the gallbladder zone. At times a sensation of pulling, sticking or dragging leads to the suspicion that adhesions to adjacent viscera may be present.

2. Bowels. Constipation was obstinate in 62.7 per cent. of the instances of pericholecystitic adhesions in this series. There was diarrhea in 9.8 per cent. and normal motions in 27.4 per cent. These figures closely approximate those instances of gallbladder disease in which pericholecystitic adhesions did not exist.

3. Nausea was an annoying symptom in eighty-nine cases, or 18.2 per cent., and vomiting in 106 cases, or 21.7 per cent. With respect to these symptoms, there was no appreciable difference between the stone and the nonstone cases, but the frequency is considerably less than in instances of gallbladder disease in general (45.2 per cent.).

4. Signs of Obstructed Bile Flow. Jaundice was constant or intermittent in ninety-two, or 18.8 per cent., of the cases. There was a possible history of jaundice in forty other cases (10.2 per cent.). Except in the cancer cases, constant jaundice appeared to be rather more frequent in the stone cases than in those in which duct obstruction was caused by pericholecystitic adhesions. In the case of malignant gallbladder adhesions, jaundice was persistent in thirteen of the twenty-one cases. Clay colored stools were noted in sixty-one cases, or 12.4 per cent., and bile pigment in the urine in seventy-six cases, or 15.5 per cent.

5. Abdominal tenderness was recorded in 91 per cent. of cases. There was a palpable gallbladder tumor in twenty-nine instances and an enlarged palpable liver in eighteen cases.

6. Gastric Function. Complete test meal analyses are available in 370 cases. The emptying power of the stomach was interfered with in twenty-six cases, or 7.1 per cent. These gastric extracts exhibited persistent twelve hour food retention. In such cases, pericholecystitic adhesions involved the pylorus, the duodenum, the cystic and hepatic ducts, the omentum and the liver. There was gastric retention in seven of the twenty-one malignant gallbladders.

These facts respecting gastric emptying power are of considerable diagnostic significance when considered in relation to such information returned in disease of viscera in the right upper abdominal quadrant other than the gallbladder. In our series of gastric cancer, some degree of twelve hour food retention was proved in 71 per cent., in ulcer of the duodenum in 52 per cent. and in gastric ulcer in 39 per cent. It is evident that even though pericholecystitic adhesions to the duodenum or the stomach may be very extensive, the lumen of the viscera is but infrequently grossly occluded.

7. Gastric Acidity. The average free hydrochloric acid was 35.1, with a range of from 0 to 140. There were forty-five instances of achlorhydria, of which only seven were malignant cases. Total acidity averaged 43.2, with a range of from 4 to 146. Combined acidity averaged 4.7, with a range of from 0 to 19.

It is apparent from the foregoing observations that grossly the gastric secretion does not greatly vary from the normal in this type of case, although there is a rather high proportion of achlorhydrias. There are numerous instances of high free hydrochloric acid—quite as high as occurs in such lesions as duodenitis or ulcer of the duodenum or of the stomach. The test meal analysis may closely approximate that of peptic ulcer, with the exception that blood is uncommonly detected in gastric extracts.

ROENTGEN-RAY EVIDENCE

By roentgenograms, in which nonmalignant pericholecystitic adhesions involve the first part of the duodenum or the pylorus, it is not possible to differentiate the resultant deformity or malposition from anomalies due to chronic ulcer of duodenum or pylorus. In fact, as we have pointed out, peptic ulcer was concomitantly present in eleven of the fifty-seven cases (19.2 per cent.), in which the adhesions involved the pylorus and the common ulcer-bearing area of the duodenum. Thus in nearly one of five cases, a roentgen ulcer picture may modify the possible deformity from pericholecystitic adhesions. Roentgenograms may thus indicate displacement and fixation of the stomach to the right, deformity of the duodenal cap or pylorus, stenosis of the pylorus or duodenum, dilatation of the stomach or duodenum, and angulation of the antrum, the pyloroduodenal junction or of the duodenum itself. Alterations in gastric peristalsis, as a consequence of pericholecystitic adhesions even of a nondeforming or nonstenosing nature are by no means uncommon. The hyperperistalsis with rapid gastric or duodenal emptying or with obstinate pyloric, gastric or duodenal spasm may be quite as pronounced in the case of acute or subacute gallbladder affections with adhesions, as when duodenal or pyloric ulcer is present and associated with them. It may, however, be emphasized again that deformity of the stomach due to pericholecystitic adhesions is most common at the pylorus. Very infrequently the pericholecystitic adhesions reach the gastric antrum or parts of the viscus in which peptic ulcer is common. Similarly, the duodenum was involved by pericholecystitic adhesions in only nineteen out of ninety-seven cases, in its first portion, that is, the most frequent location of duodenal ulcer.

In 211 cases of gallbladder disease complicated by adhesions, of which roentgen study was made, the duodenum showed stenosis in ten, sharp permanent acute angulation of the intestine in seven, dilatation of the first two-thirds in twenty-six, possible deformity in forty-nine and possible malposition or fixation in twenty-three cases. In this group of patients there was gastric retention of the opaque meal in thirteen instances.

When the pylorus or stomach was involved, there was deformity or malposition in eighteen out of thirty-two cases, stenosis in twelve, with three malignant cases, and six hour opaque meal retention in ten cases. Deformity of the pylorus or duodenum was always most pronounced and persistent in the malignant cases or in those in which pericholecystitic adhesions complicated a greatly distended and enlarged gallbladder.

As in the case of roentgen examination of lesions other than pericholecystitic adhesions, it is important to make serial plates, with the patient in different positions, before and after the administration of such antispasmodic medicine as atropin or belladonna. This procedure will prevent local or general spasms of the stomach or duodenum from being considered as definite persistent deformities and will aid in establishing the fact that the deformity or malposition is constant or is localized.

If roentgenograms show enlarged gallbladder, definite gallbladder contour, or stone shadows, then, in the absence of clinical data indicating organic disease of the stomach or duodenum, gross anomalies of these viscera may with a fair degree of safety be interpreted as being due to pericholecystitic adhesions.

Pericholecystitic adhesions involving the colon are neither frequently nor readily demonstrated by roentgenograms. If the clinical history points to gallbladder disease, especially in association with evidences of colon stasis, and if roentgenograms show an enlarged gallbladder shadow or stones, then anomalies of position of the hepatic portion of the colon, if persistent in plate series after the administration of atropin or belladonna, may be interpreted as arising from pericholecystitic adhesions. Such anomalies are more pronounced in instances of malignancy of the gallbladder invading the colon.

Fluoroscopically, deformities of contour or malposition of viscera due to pericholecystitic adhesions are more accurately detected than by plate studies. Not rarely one may definitely prove the absence of primary lesion, such as ulcer or cancer, in the stomach, duodenum or colon, and by palpatory manipulation during the examination (particularly when the study is made in several seances) one may demonstrate that displacements, alterations in contour, angulations, spasms or stenoses are dependent on causes extrinsic to the viscera. Comparison between the observations made before and after the administration of antispasmodic drugs is of such great value that the procedure should be adopted as routine, if mistakes are to be avoided and accuracy in diagnosis sought.

ABSTRACT OF DISCUSSION

Dr. Robert T. Morris, New York: Dr. Smithies referred rather briefly to points which require rather more elaboration. Rosenow has shown that this group of adhesions bears relation to the elective affinity for structures in the vicinity for toxins. This class of adhesions may be grouped under what I have sometimes called "cobwebs in the attic." These cobwebs in the attic do not necessarily accompany an acute inflammatory process. Even a burn at a distance may give rise to adhesions in this vicinity, because toxins are being collected there by elective affinity. After a burn a toxalbumin may be produced, not, perhaps, different in its ultimate effect from the enzyme from an infected tooth root, from the enzyme from bacteria in the tonsil, from enzymes from the colon on their way out. All being grouped in this vicinity by elective affinity produce a second physiologic effect; they call out antibodies, and the antibodies are called out in such an amount that destructive cellular processes result; we then have desquamation of endothelium and plastic exudation, and this forms adhesions, even without the patient being aware of the process at all. There are acute symptoms in some of these cases, in other cases practically none. The symptoms may simulate very closely those of gallstones, and I have seen very many mistakes made by younger surgeons in making a diagnosis of gallstones. Do not make a diagnosis of gallstones; make a diagnosis of cholecystitis. How are we going to prevent recurrence of adhesions after we have separated them, or after we have removed a gallbladder? We must look for the original focus of infection and remove it. Shall we use mechanical means for preventing a recurrence? In cases where adhesions have been very extensive, I believe yes. My first choice is the Senn omental graft; my second choice is Cargile membrane; my third choice is to make an aristol film. The oils are *not* to be used in this vicinity, because oils catch leukocytes, which are thrown out for purposes of repair, and prevent their organizing and carrying new endothelium over the surface.

Dr. G. A. Friedman, New York: Recent work on the same subject as that of Dr. Smithies' paper and my experience have convinced me of the possibility of diagnosing pericholecystitic adhesions without waiting for exploratory laparotomy. The points are the tender spots or pressure points in the axillary, scapulary and posterior median lines to the right. Tender spots may not be detected in the region of the gallbladder. From the presence of these spots, cholecystitis was diagnosed by my house physicians without the aid of roentgen rays or other examinations. After carefully examining and comparing the spots at the right side with corresponding spots at the left side, and when repeated examinations have convinced you of marked tenderness in the axillary and scapulary lines, you may be sure that operation will reveal, if not gallstones, at any rate, cholecystitis or pericholecystitic adhesions. I do not claim this sign as my discovery. Boas pointed it out years ago, but it was never utilized in the proper way for diagnostic purposes, especially in atypical cases. I have frequently diagnosed cholecystitis in patients who never have had any pain. They presented only the nervous symptoms, such as sensitiveness in the stomach, as the sensation of a load or stone.

I have demonstrated that these pressure points are to the right in the scapulary line, just at the level of the gallbladder, and also near the posterior median lines. Usually the tender spots are found in the axillary line alone; very often, however, in both the axillary and scapulary lines, and occasionally in the axillary, scapulary and posterior median lines. I seldom find these spots in the region of the gallbladder. When repeated pressing on this region fails to disclose tenderness, it is falsely concluded that there is no cholecystitis.

Dr. Nathan Rosewater, Cleveland: May I ask Dr. Friedman how he distinguishes those pains from pains that would occur in rheumatic muscles, or, say, from some other cause?

Dr. Friedman: I have never found the aforesaid pressure points in muscular rheumatism or in the neuralgias, unless it is an intercostal neuralgia, and then the diagnosis is usually obvious. I had three cases of hepatic syphilis in which they were absent; in carcinoma of the pancreas with enlargement of the liver, and in secondary carcinoma they are absent; they are absent in all conditions except in cholecystitis.

Dr. Mary Dunning Ross, New York: I wish that some one would tell us a little more in detail how to get in back of these bacteria before the enzymes and the antibodies have done their damage.

Dr. William Van Valzah Hayes, New York: The cases that interest me particularly are those with adhesions or bands running from the gallbladder to the duodenum and the colon. These patients may have no symptoms whatever for a considerable period, and later on they develop attacks almost exactly simulating gallstones. There is sudden violent colicky pain and distress, and the patient is put to bed incapacitated. On operation no sign of ulcer, no sign of thickening of the gallbladder, no distinct evidence of any inflammatory condition existing at the time is found. Bands are found, and to secure for the patient complete and permanent relief these bands are divided transversely and sutured longitudinally.

Dr. Roland Hazen, Paris, Ill.: I have been doing work in repairing a ptosed colon, and found a great deal of trouble with adhesions connecting the colon with the stomach, duodenum, gallbladder and ducts. The work that I have been taking up has been based more on the anatomic arrangement of the normal fixed colon. I take the view of a colon as though looking at it from behind, and study what there is that prevents the colon, either normal or ptosed, from getting all the way down. In dissecting a 5-month-old fetus I found that the descending colon had already fused; it was firmly fixed; I could peel it away without difficulty. The ascending colon was very slightly fixed. These adhesions occur between the outer layer of the mesocolon or the ascending colon and the flank. In addition to that adhesion I found a little band of adhesion that ran from the hepatic flexure up to the gallbladder, not involving the entire gallbladder, but rather a thickening of the edges, and was evidently giving some support, pulling on the descending and ascending colon. There was some node on the surface of the liver, which is undoubtedly the beginning of the formation of the hepatocolic ligament. The only thing that held was this attachment to the end surface of the liver, which involved the bile vessels. Take that in the adult subjects; we have a case in which we have not had any fusion of the ascending colon, but the hepatocolic ligament is developed, and after adult age, with the enlargement of the pelvis, the colon will tend to sag if it is not fastened to the ascending colon; the strain will come on the ascending colon and all bands which go to the liver. Thus we are going to have congestion. Just what rôle the bacteria will play in that case which develops purely from a mechanical start on this basis, I do not know, but undoubtedly bacteria will have some part in that development; but primarily the trouble in these cases is not due to the infection; it is mechanical. On that basis I have examined the adhesions very carefully, and find that by drawing up the hepatic plate you will find that the adhesions radiate from the hepatic plate to the gallbladder, and in cases of cystolith of the gallbladder the adhesions radiate from the gallbladder out in a different direction, and those adhesions attach to something. In the final cases they attach to the gallbladder. If you look into these cases you will find that a great many are due to the colon trying to hold onto something to keep it from falling down. Sometimes the colon is held up by the adhesions, so that these persons have not developed the general symptoms of ptosis.

Dr. Frank Smithies, Chicago: The points which Dr. Morris brought out are referred to in the text. Dr. Friedman's observations correspond in a certain degree to the zones of peripheral tenderness or hyperesthesia spoken of by Head and others some years ago. Very likely the points are better made out in gallbladder disease, because we have to do with an infective process, which is frequently quite active. The question of pain indicating gallbladder disease I have emphasized in previous work. Less than a third of our cases of gallbladder disease gave the so-called classic symptoms of gallstones, or gallbladder malfunction.

Dr. Rose asks how we are to control the bacteria in the gallbladder wall. Most people come to the doctor after they are sick. The bacteria have already done damage then. If we pay more attention to the complications of the infectious diseases occurring in early life I feel that we can prevent some of the serious damage done later on in the gall tract.

Dr. Harris' explanation of the adhesions along embryologic lines is very interesting. I think adhesions follow these directions because the lymph stream and the blood stream follow natural bridges, and some of these ligaments are natural bridges.

As to the effect of ptosis in causing pain, I am not so pronouncedly in agreement with the doctor, because I have begun to forget about nine tenths of what I learned twenty years ago about ptosis. We see fewer so-called ptoses now than formerly, and we correct fewer ptoses than we did. I pay less attention to ptosis every day. If the bowel function is normal and the stomach function is normal, I do not care where the viscera are placed.

Operation and Low Blood Pressure.—An operation should not be done to a shocked man unless his blood pressure has been artificially raised above the critical level. Blood transfusion or intravenous injection of the gum-salt solution may be done at the start of an operation, and the pressure may thus be prevented from falling.—*Review of War Surgery and Medicine.*

RÔLE OF PASTEURIAN METHODS IN PROPHYLAXIS OF INFECTIOUS DISEASES IN THE ARMIES

ESPECIALLY IN THE ARMY OF THE ORIENT AT THE DARDANELLES AND IN MACEDONIA *

P. F. ARMAND-DELILLE, M.D.
Médecin des Hôpitaux de Paris; Médecin Major, French Army
PARIS, FRANCE

The past forty years have seen a complete modification of the methods of hygiene in public health under the influence of the progress of bacteriology. It is surely not paradoxical to say that the present war, with its great agglomerations of men, could not have been possible without the aid of a prophylaxis against infectious diseases.

The expedition to the Orient furnishes us with the most striking demonstration. I was appointed in 1915 as chief of the Service of Bacteriology and Epidemiology for the armies, with a well-equipped bacteriologic laboratory. All our army laboratories are indeed standardized with the help of the Institut Pasteur.

I shall not speak of the serotherapy against diphtheria, which has been employed not only curatively but also prophylactically in the control of epidemics. Nor shall I more than mention the serotherapy of tetanus, which has been systematically practiced among all the wounded since the first twenty-four hours of the war. The serotherapy of cerebrospinal meningitis and of dysentery has also rendered us great service, although the great variety of bacilli has made the latter much less efficacious in certain cases.

VACCINATION AGAINST TYPHOID

The vaccination against typhoid and against cholera has been, on the other hand, of much value. At the beginning of the campaign of 1914, it was only the forces of the regular army who were vaccinated against typhoid, so that numerous cases developed among the reserve. We are able, however, to stop this epidemic by the vaccination of the entire army, employing the antityphoid vaccine of Vincent.

We also encountered among the men of the army of the Orient a certain number of cases of paratyphoid A and B, both in Saloniki and at the Dardanelles. From March, 1916, we made use of the paratyphoid vaccine "T. A. B." of Widal, by which means we eradicated all typhoid and paratyphoid, to such an extent that during the latter half of 1916 the proportion was but one in ten thousand per month, and the cases observed always occurred in individuals, nonvaccinated for one reason or another.

Since May, 1917, we have employed the lipovaccine of Pinoy and Le Moignic, which has had the added advantage of requiring but a single dose. I have seen with much interest that studies of this vaccine have been made in this country by Whitmore, Fennel and Peterson of the United States Army.

PROPHYLAXIS IN CHOLERA, AMEBIC DYSENTERY AND PLAGUE

Vaccination against cholera has been practiced among all the soldiers and officers of the expeditionary forces to the Orient, and I had the opportunity of establishing its efficacy in an epidemic arising among the civil population in the town of Koritza on the Albanian frontier in August, 1916. The town comprised almost 10,000 inhabitants and the epidemic was rather severe, with a death rate of from seven to ten persons per day, during the three weeks before we arrived. I sent one of my assistants, Major Lemaire, with the technical councilor, Major Sarraillhè, who was able in the first twenty-four hours to isolate in seven samples the vibrio of cholera, entirely characteristic and verified by a high agglutinating experimental serum from the Institut Pasteur.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

With the aid of a local physician, these officers vaccinated the entire indigent population in the period of one week. This resulted in a complete arrest of the epidemic in less than three weeks. Three months later, a French division was billeted in this region without the development of a single case of cholera. The same results were obtained at Corfu by other French medical officers, who succeeded in stopping a similar epidemic that had been introduced by the Serbian soldiers.

At the Dardanelles and in Saloniki we observed a certain number of cases of amebic dysentery by the discovery in the stools of the adult amebas and cysts. These cases were treated by the injections of emetin with complete success.

In order to prevent contamination of fecal origin, we organized a system for the incineration of all refuse and, as much as possible, of fecal matter. When that was not possible, chlorination with lime was employed.

The prevention of plague was foreseen by the installation of a special laboratory in which my assistants performed necropsies on the bodies of all the rats secured each day by a group of men designated for that purpose. Fortunately, we found only a small number of rats infected with the *Bacillus pestis*. There was but one case of plague observed during the year 1916, and that in an indigent stevedore. The house was completely disinfected and the rats of the whole quarter were systematically destroyed.

With the object of coordinating all the services of prophylaxis in the Orient, there was established shortly after our arrival a high commission of preventive medicine and hygiene, which met each week and at which were represented the chief of the medical service of the French army, of the British army, of the Serbian, the Greek and the Italian armies, as well as the director of civilian public health of Macedonia.

PREVENTION OF TYPHUS

One of the most important points was the prevention of exanthematic typhus. The great Serbian epidemic did not reach Saloniki, but we observed a few cases in the Serbian army, as well as two cases among the civilian population of Monastir. Afterward an epidemic with thirty cases and fourteen deaths appeared in the Russian brigade.

Among the French troops there were observed only a few cases of relapsing fever. These few cases were contracted by the soldiers from the civil population. Relapsing fever, which is due to the spirochete of Obermeier, is, in fact, very frequent in Macedonia. During the first Balkan War in 1912, 50 per cent. of the Greek troops located in Macedonia were rendered useless by reason of this infection during the last months of the winter. Exanthematic typhus and relapsing fever are transmitted by lice, a fact now thoroughly established. By means of our systematic measures of disinfection, we were able almost completely to eradicate lice from the French troops. These measures consisted in the installation of shower baths for all the soldiers and the disinfection of their clothing. For the troops in the resting cantonments, the disinfection was accomplished by the so-called "groupes bains douches desinsectisation de Geneshe-Hercher brazier," which consist of 3-ton trucks carrying an apparatus for twelve shower baths and eight autoclaves for disinfection. This permits of passing the men serially and the delousing of one battalion in ten hours. For the troops confined to the trenches, when the nature of the country does not permit of the transportation of the larger apparatus, we employ a smaller one, the "appareil bain douches portatif de Charles Leblanc" of four baths, which weighs only 200 pounds and can be carried on a mule. For the destruction of the lice in the clothing, we employ simply ironing. This system, introduced by Dr. Sarraillhè, is very useful and efficient, if it is repeated at least once a week. The cycle of growth from the egg to the age of reproduction of the louse is twelve days. The destruction is produced by a type of tyndallization, that is to say, that the first ironing destroys a certain number of eggs and lice; and when the process is repeated each week, the progressive generations are also prevented from reaching maturity. We were able to demonstrate in a number of regiments that this method removed the lice effectively in 95 per cent. of the cases.

The epidemic which appeared in the Russian brigade was arrested by the creation of a sanitary barrier which was easily enough established in such a desert region with stations for disinfection and a second hospital for disinfection previous to discharge, furnished with the apparatus just described.

PROPHYLAXIS AGAINST MALARIA

The prophylaxis against malaria was unfortunately less successful, at least during the first year, because of the military conditions in the country, and on the other hand the difficulties in securing prophylactic medicines, quinin, for example, in sufficient quantities. In the winter of 1915 and 1916 I proposed an antimalaria campaign similar to that carried on by Major Craig at Panama. Macedonia, and particularly the valley of the Vardar, is perhaps comparable to the most dangerous tropical regions. At that time I was able to establish the fact that there were 20 per cent. of carriers in a village housing Greek refugees at Zeitenlick, 5 km. from Saloniki, in the neighborhood of the French and English camps. And the endemic index determined by the presence of splenomegaly, studied by Major Mauban, was nearly 50 per cent. among the children. For the 3,000 inhabitants of this village we had the opportunity of practicing quinin sterilization, and were able to diminish very markedly the contamination of the troops stationed in the camps. This was, unfortunately, not possible with the troops assigned to the trenches in the valley of the Vardar and the Butkova. For this group of men, preventive quininization was instituted, but was not efficiently carried out in certain regiments. In addition, the men were housed in tents with insufficient mosquito netting, so that the contamination was considerable. Further, it was impossible to have sufficient screening for the barracks, the clapboarding of which was poor. An insufficiency of crude oil did not allow of this treatment of the marshes, which were frequently 50 miles in extent, and those in Macedonia were interspersed with numerous marshy-bordered lakes. From July to October, 1916, we encountered a serious epidemic among the French as well as the English troops, with a certain number of cases of the pernicious type. It is necessary to add that our microscopic examinations of the blood demonstrated to us in September and October that the proportion of malignant tertian malaria was 95 per cent.

In 1917, the conditions were such as to allow of a reduction in the number of cases of malaria, thanks to a special service of prophylactic measures against malaria organized with the aid of M. Justin Godard, undersecretary of the Service de Santé. The plan was prepared by Dr. Edmond Sergent, chief of the Pasteur Institute of Algiers; Dr. Etienne Sergent, chief of the Antimalarial Service for Algeria, and Dr. Segroux of the Pasteur Institute of Paris. Following a mission for the study of conditions made by Dr. Sergent and myself in Macedonia, the service was organized with the following personnel: twenty physicians who had specialized in questions of tropical medicine, a woman physician who could talk to the indigent population, 300 nurses to supervise the quininization, all for the mechanical protection of the cantonments, and an engineer with a force of peons for the drainage of the district. The physicians were distributed in their respective districts and were consulted on the location of the camps, which were more easily chosen during the second year of the occupation.

Furthermore, the screening of all the base barracks was accomplished during the winter. All the soldiers were furnished with large individual mosquito nets and their use was enforced by the physicians and nurses under pain of severe punishment. Finally the drainage of all the small marshes neighboring to the camps was carried out. The quininization of the soldiers and of the civil population of the villages in proximity to the camp consisted of 0.4 gm. per day, effectively supervised. I am forced to add, however, as a result of my experience among a certain number of persons, that the preventive quininization even at this dosage is not sufficient to protect against tertian malaria, if the number of infections is considerable. This was the case in Macedonia, where the *anopheles* is extremely numerous. Thanks to these measures, it was possible to reduce to 75 per cent. the number of cases during 1917, and the pernicious cases occurred but rarely.

CONCLUSION

I may say that the complete eradication of malaria in Macedonia, impossible during the war, would require several corps of excellent engineers, a hundred million dollars and twenty years of labor. We hope it may be accomplished in the future, but at the present time for the protection of our troops we can only employ the mechanical measures against the anopheles, quininization and the drainage of the smaller marshes.

THE PRESENT STATUS OF THE OPERATIVE TREATMENT OF CHRONIC FRONTAL SINUSITIS *

T. W. MOORE, M.D.
HUNTINGTON, W. VA.

Today, obliteration of the frontal sinus is attempted only in those cases in which there has been extensive necrosis of the bony wall, and our treatment is directed to establishing ventilation and drainage.

Various operators have devised new methods and modified old ones of opening the frontal sinus intranasally since Schaeffer, in 1890, published his method of penetrating the floor of the sinus through the ethmoid cells. This method had been abandoned until it was revised and improved in 1905 by E. Fletcher Ingals, who later used gold tubes. In the same year it was improved by Segura, we are told by Watson Williams and also by Ingals in their interesting historical reviews of the subject. In 1906 Max Halle described his operation of removing part of the nasal crest with burrs. He has since modified his method by making a flap of mucoperiosteum, which has not proved advantageous in the hands of other operators. Vacher, Goode, Sullivan, Thompson and other rhinologists have added new methods and different technic.

Sluder, by his ethmoid knife operation, aided us. Later Mosher gave us much assistance, as the result of his painstaking anatomic studies, by simplifying the entrance to the sinus intranasally by the method which bears his name, through the agger nasi cell, and according to his later recommendation, through the upper part of the anterior end of the middle turbinate. This has again been made easier, I think, by the curet devised and used by Faulkner.

Then, Watson Williams advised opening the anterior ethmoid cells by cutting through the anterior end of the middle turbinate at its attachment to the outer nasal wall with biting forceps. In discussing Williams' paper, Tilly stated that he removed the anterior end of the middle turbinate. This, as all operators know, must be done when the space between the septum and nasal wall is very narrow. Cases of this type have always been the most difficult for us to handle. Williams also advised breaking down the ethmoid cells posterior to the ostium, as was recommended in greater detail of instrumentation and technic by Freer in 1915. As far back as 1911, Killian stated that he no longer performed the operation bearing his name. Beck's osteoplastic flap operation gives us an opportunity to work from the sinus downward into the nose, while observing each step taken. The fear of the terrible deformity that would result if the bony flap failed to unite has made this too formidable a procedure to me.

When there is extensive destruction of the bony walls, especially the external wall, it is not practical to adhere to any special type of operation. I remember some years ago operating on a beautiful woman of about 40, a time when women are much interested in their personal appearance. When the incision was made, I found a large sequestrum of bone covering the entire sinus, and including much of the superorbital ridge. In fact, nature had made a Beck bony flap. When this was removed, there was a step about half an inch deep in the median line. I was much puzzled as to what to do, but chiseled off the anterior wall of the other frontal sinus, obliterating both. Fortunately for me, the patient was pleased with her appearance afterward.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

LOTHROP'S OPERATION

The most distinct advance made, I think, in the surgery of the frontal sinus, is the operation devised and advocated by Lothrop. This offers all the advantages of the intranasal operations, and at the same time permits direct inspection of the sinuses and also of the work, step by step, as it is accomplished. It will be remembered that Lothrop recommends first the removal of the anterior end of the middle turbinate and the breaking down of the anterior ethmoid cells with a curet, which frequently gives a free opening into the frontal sinus. This procedure he follows ten days or two weeks before the more radical operation is done. This drainage, as we know, in a large percentage of cases will effect a cure.

His more radical operation is done as follows: A pledget of cotton saturated with a 4 per cent. cocain in epinephrin solution, is inserted in each nostril as far forward and as high as it can be placed. This lessens the bleeding during the operation. Under general anesthesia a curved incision, about 1 inch in length, is made through the eyebrow, beginning at the superorbital notch and extending over to the nose, the periosteum is carefully elevated, and a Vail or Jansen retractor inserted. An opening is now chiseled through the bone into one sinus at the naso-orbital angle, or Ewing's point. The sinus is now carefully inspected and any pus, polypi or granulation tissue removed, care being taken to preserve as much of the mucous membrane intact as is possible. A probe is now passed into the nasofrontal duct and used as a guide, while with curet, rasps and burrs, the cells anterior to the nasofrontal duct are broken down, and the mass of dense bone at the root of the nose, formed by the nasal process of the superior maxillary, frontal and nasal bones, is removed.

The partition between the sinuses is broken through and removed and the intranasal floor of the second sinus removed, whether it is diseased or not. At the same time the operator takes away the upper portion of the nasal septum, thus making a large passage from the now single sinus into the nose, which may be entered readily from either nostril. The external wound is now closed, without packing, and a pressure bandage applied and left on for twenty-four hours. when a dressing of cotton and collodion is applied and permitted to remain for five or six days, when the stitches are removed.

There is no after-treatment required, except a nasal (*not intrasinus*) douche to remove the increased secretion, due to the irritation produced by the operation. This usually subsides in two or three days.

MINOR ADVANTAGES OF OPERATION

There is no question in my mind but that frontal sinuses which have free drainage and ventilation do much better without being probed or treated in any way, which is usually distressing to the patient. Freer lays stress on this.

The burrs and rasps that have been devised by various operators, Lothrop, Tilly and Lynch, have added to my armamentarium.

We must never overlook the roentgen-ray picture in these cases, preferably stereoscopic pictures. While I have not acquired the proficiency of Beck in interpreting these plates and in being able to say so exactly by them what the pathology is, still they are invaluable to me.

Dr. Fletcher Ingals in a paper last year quotes some one as saying, "The value of an operation is not what it accomplishes in the hands of its inventor, but what can be done with it in the hands of other operators." Hence, my advocacy of this operation, which has proved very satisfactory to me, and to my twelve patients on whom I have used it, six of whom had been operated on by myself or some other rhinologist previously, without being permanently relieved.

An objection has been offered to opening a healthy sinus for increased drainage, for fear that it might be infected. My answer is that it does not, or did not become infected in any of my twelve cases, in only three of which both sinuses were involved.

I examined one of my first patients recently, now more than two years since the operation was performed, and there is still a free opening and the roentgen-ray picture shows a healthy sinus, although the patient had to have an operation on a maxillary antrum.

The variations in the anatomy as shown in Shambaugh's recent paper should make us hesitate to attempt to open all sinuses intranasally without seeing just what we are doing. In one of his specimens, one sinus had no outlet except into the other frontal sinus.

ABSTRACT OF DISCUSSION

Dr. Frank R. Spencer, Boulder, Colo.: We have all been forced to realize how rapidly an opening into the frontal sinus tends to close, even when we have been successful in enlarging the nasofrontal duct, and this closure soon defeats free ventilation and drainage. For this reason all intranasal surgery, on this sinus, is more or less unsatisfactory. The Killian radical operation has become very unpopular except in rare cases, on account of the disfigurement. This shortcoming has been met by the Lothrop operation. However, I should like to emphasize the importance of making the opening into the frontal sinus no larger than is necessary for efficient work, so as to avoid disfigurement, and the importance of making the opening into the nose, from the sinus, as large as the nasal anatomy, in any given case, will permit. Since the former is a temporary opening and the latter a permanent one the reason for this is self evident.

Another feature, which Dr. Moore mentioned briefly, is the importance of removing thoroughly projecting bone in the region of the frontal process of the superior maxillary. This can best be done with the burr. If left undone it gives rise to granulations which tend to close even the large double opening.

Dr. George E. Shambaugh, Chicago: I am in accord with the conclusions of the essayist regarding the question of an external operation. I am coming more and more to the conclusion that satisfactory relief for most of the frontal sinus cases can be reached by intranasal work. It is very seldom that we are required to do any operation for an acute sinus, but where there is recurring acute sinus infection the first step is the removal of the anterior and of the middle turbinate. In chronic cases this should be followed by an exenteration of the anterior ethmoid cells. With this accomplished one usually has little difficulty in making a satisfactory widening of the nasofrontal duct. The use of rasps are of great assistance in this work. In most of the cases of chronic sinus empyema we can relieve a patient of the larger part of his discomfort, even in cases in which the complete cure of the chronic process does not result from the nasal operation. In my opinion the external operation should be reserved for cases in which carefully carried out intranasal work fails to relieve the patient from annoying headache and in cases in which there is a threatened intracranial complication. Such cases will arise only exceptionally in one's experience.

Dr. James J. Pattee, Pueblo, Colo.: Frontal sinusitis, requiring operation, is a troublesome affection, and the operation of choice should be determined with care. From a general survey of the published opinions there is, in my judgment, a progressive increase in the number of intranasal operations with a corresponding lessening of the external. I am in accord with this order of things. I agree with Dr. Shambaugh that it is applicable in the vast majority of cases. In rare cases we must resort to external measures.

The Killian operation fails occasionally, even in the hands of our best operators. It frequently produces much disfigurement and in some cases fails to afford ample permanent drainage, the feature on which its greatest claims are based. Dr. Ingals' statement is very true. The intranasal operation requires intimate anatomic knowledge and much experience. The narrowest part of the nose is on a plane with the canthi. The Lothrop operation has the advantage of opening the sinus very near this point, a great advantage. The Lothrop operation permits of thorough work; establishes adequate drainage; affords the best vision, and offers the most direct route to the site of greatest difficulty and danger. It permits healing in the shortest time and minimizes untoward after-effects.

Military Medicine and Surgery

THE TONSILS AS FOCI OF INFECTION IN STREPTOCOCCUS HEMOLYTICUS CARRIERS *

H. J. NICHOLS, M.D.
Lieutenant-Colonel, M. C., U. S. Army
AND
J. H. BRYAN, M.D.
Major, M. C., U. S. Army
WASHINGTON, D. C.

The study of hemolytic streptococcus infections, which has been stimulated by the Army experiences of last winter, naturally includes the subject of carriers. We have done some work in this field and are convinced that the tonsils play a part that should be emphasized. It has already been shown that throat swab cultures demonstrate the presence of hemolytic streptococci in various percentages of individuals and that hemolytic streptococcus complications, for example, in measles, occur only in those with positive throats.[1] Throat swab cultures for hemolytic streptococci, therefore, have a practical value in the maintenance of clean and infected wards which has been confirmed by experience at this hospital.

INFECTION OF THE TONSILS

With the established importance of positive throat cultures as a starting point, our attention was directed toward localizing the focus of infection if there is one. For this purpose we made swab cultures in positive throat cases from each side of the nose, from the pharynx, from each tonsil and from the saliva. In making the nasal cultures, the swabs were passed into the nasopharynx. The results, which are shown in Table 1, were striking. The cultures of nasal swabs were either negative or showed a few hemolytic streptococcus colonies; the pharynx cultures were moderately positive; those of the saliva were slightly so, but the tonsil cultures showed in every case a rich growth of hemolytic streptococci. In the isolation and identification of hemolytic streptococci the methods adopted by the Medical Department of the United States Army were followed.[2]

TABLE 1.—RESULTS OF SWAB CULTURES IN POSITIVE THROAT CASES *

Case	Right Tonsil	Left Tonsil	Pharynx	Saliva	Right Nostril	Left Nostril
1	+	+++	—	—	—	—
2	++	+++	+	—	—	—
3	++	++	++	+	—	—
4	++	++	++	—	—	+
5	++	++	+	—	+	+
6	+++	+++	++	+	+	—
7	++	++	+++	+	+	—
8	+++	+	+++	—	+	+
9	++	++	+++	—	+	+

* Positive findings are thus indicated: +, few colonies; ++, many colonies; +++, innumerable colonies.

These results pointed to the tonsils as possible foci of infection. One hundred pairs of excised tonsils were then examined by means of crypt cultures made with a platinum loop. Seventy-five pairs were found positive. The degree of infection in one or both tonsils of each pair was found to be as given in Table 2.

TABLE 2.—DEGREE OF INFECTION OF DISEASED TONSILS BY HEMOLYTIC STREPTOCOCCI

Pure hemolytic streptococci	31	70%
Predominating hemolytic streptococci	23	
Many hemolytic streptococci	16	
Few hemolytic streptococci	5	
No hemolytic streptococci	25	

These tonsils were removed on clinical grounds on account of size, presence of discharge from the crypts, cervical glandular enlargement and possibility of focal infection and not on account of the carrier state except in a few instances. The results of this series of examinations made it clear that diseased tonsils harbor hemolytic streptococci in a large proportion of cases.

The condition of the surface of tonsils was then compared with that of crypt contents in regard to streptococci, and it was clearly shown that the ordinary throat swab cultures may be negative while loop cultures from the crypts may be positive. The findings were:

> Normal cases, 50; percentage of throat swab cultures positive, 28; percentage of tonsil crypt cultures positive, 50; percentage of error in throat swab cultures, 44.

Additional evidence of the importance of the tonsils in carriers is found in the results of throat cultures taken after tonsillectomy, which will be referred to later.

Out of twenty-five cases of typical acute follicular tonsillitis, only one failed to show a rich culture of hemolytic streptococci. We believe that the ordinary case of tonsillitis is most frequently caused by hemolytic streptococci, and that the organisms in many cases persist and reinfect the individual or spread to others.

In persistent carriers of any infectious disease, some focus seems necessary, as pathogenic organisms do not seem able to live indefinitely on healthy tissue. In typhoid and cholera carriers the gallbladder, liver or kidneys are recognized foci rather than the intestine or urinary tract as a whole. In diphtheria carriers the tonsils are being recognized as the principal focus.[3] We believe the same is true in streptococcus carriers. The possibilities, of course, include the nose, the sinuses, the gums and the adenoids; but in our experience the tonsils are by far the most frequent foci. Sections made of positive tonsils have usually shown erosion of the epithelium of the crypts with exudate.

---

* From the Laboratory Service and the Ear, Nose and Throat Section of the Surgical Service of the Walter Reed General Hospital, Washington, D. C. In this work the writers were assisted by: Capt. C. O. Stimmel, Capt. William H. Huntington, Lieut. S. A. Alexander and Lieut. E. Sturm.

[2] Methods for the Isolation and Identification of Streptococcus Haemolyticus, Adopted by the Medical Department, U. S. Army, June 1, 1918.

IDENTIFICATION OF CULTURES

One hundred strains of streptococci have been studied by Captain Stimmel for cultural reactions in His sugar mediums with results shown in Table 3. In this work each tube was checked for purity and growth by smears and by transfers to blood agar plates. In case of contamination of any tube or lack of growth in negative tubes, the work was repeated. Fresh serum was found necessary for good growth, and serum water controls were used without sugar, as some serums naturally contain over 0.5 per cent. of glucose. Tests were also made for bile solubility, hemolysis in blood broth and morphology. The results were clean cut and uniform.

TABLE 3.—CULTURAL REACTIONS OF STREPTOCOCCI

Source of Strain	Number	Glucose	Lactose	Saccharose	Mannite	Maltose	Dextrin	Inulin	Salicin
Tonsil...........	43	+	+	+	—	+	+	—	+
Throat...........	26	+	+	+	—	+	+	—	+
Empyema........	18	+	+	+	—	+	+	—	+
Miscellaneous.... (middle ear, etc.)	11	+	+	+	—	+	+	—	+

In other words, no differences were found in strains from empyema fluids and surgical conditions, as compared with those from throats and tonsils. Of course, there may be differences in immunity reactions; but for the present in the prophylaxis of pneumonia and empyema, no differentiation is available. Several tonsil strains tested for virulence were low, requiring 0.5 c.c. to kill a mouse; but by mouse passage they became more virulent.

THE CURE OF CARRIERS

In our experience the only radical method of curing carriers is excision of the tonsil, which is successful except in a few cases in which other foci are present in the gums or elsewhere. The problem of chemical or mechanical disinfection has been attacked at this hospital as well as elsewhere with some enthusiasm, but a short experience has shown the futility of most measures. It has been found that a certain number of carriers on no treatment give two successive negative cultures in about three weeks. With dichloramin-T, Dobell's solution and hot alcohol, a few carriers cleared up in about the same time.

Under daily use of 25 per cent. silver nitrate, several cases became negative in about one week; but in some of these cases the crypts were still positive after negative throat cultures. In order to test the disinfecting power of silver nitrate, several excised streptococcus tonsils were submerged in 25 per cent. silver nitrate for five minutes. They were then washed in salt solution and incised, and cultures were made from the crypts. All these cultures were positive. In cases with a few open crypts, the silver nitrate treatment may be effective; but in most tonsils it is impossible to sterilize the crypts by this means.

The difficulty in sterilizing the tonsil may be realized by attempting to inject all the crypts with lampblack in paraffin; after all visible openings have been injected and the paraffin allowed to cool, incision of the tonsil will show a number of perfectly good crypts that have escaped the injection. If this is so with excised tonsils, the impossibility of mechanically or chemically disinfecting this tissue in vivo is easily understood.

The change noted in throat cultures after tonsillectomy was striking as compared with any other method. Twenty-seven out of thirty-one cases showed a second consecutive negative culture in eleven days. In the cases that did not clear up under tonsillectomy, there were foci in the nose or gums, and the cases became negative when these were attended to. No case of a carrier has been found in men who had previously had their tonsils properly removed.

COMMENT

It is evident that the removal of diseased tonsils is indicated not only for the good of the individual but also for the good of others, because it reduces the number of carriers of *Streptococcus hemolyticus.* Whether a carrier with healthy tonsils should be operated on simply because he is a carrier may be a debatable point; but in view of the lack of standards for "healthy" tonsils, it is justifiable to operate in our opinion, provided the case does not clear up in a few weeks spontaneously or under silver nitrate.

The practicability of materially reducing the number of carriers by this means is also a debatable point, as the number of carriers may be large, running at times from one third to one half of the military population. It is at least possible, however, to examine the tonsils of chronic carriers and to remove those tonsils which are manifestly diseased.

CONCLUSIONS

1. The tonsils are the principal foci of infection in throat carriers of *Streptococcus hemolyticus.*

(*a*) Cultures taken from different parts of the nose, mouth and throat show more streptococci in the tonsils than elsewhere.

(*b*) Cultures from excised tonsils show streptococci in 75 per cent. of cases.

(*c*) Crypt cultures show a higher percentage of positive results than surface cultures.

(*d*) Excision of the tonsils renders the throat negative in nearly all cases.

2. The streptococci isolated from tonsils and throats show no cultural difference on sugar mediums from those obtained from empyema fluids.

3. Excision is the only radical method of curing carriers of the infection.

(*a*) Dobell's solution, dichloramin-T and hot alcohol had little better effect than no treatment.

(*b*) Silver nitrate, 25 per cent., gave the better results in negative throat cultures, but the crypts frequently remained positive.

4. The presence of hemolytic streptococci in pathologic tonsils is an additional reason for their removal.

Obligation of Physician to Report Births.—The state protects the physician in his practice, and on ethical ground has a right to expect him to comply with the laws affecting his practice, and on legal grounds to demand the registrations of births as a matter of public welfare. Court decisions have held this many times.—W. J. V. Deacon, M.D., State Registrar, Kansas.

STUDIES ON IRRITABLE HEART

PRELIMINARY REPORT

LOUIS M. WARFIELD, M.D. (Milwaukee)
Major, M. C., U. S. Army
AND
FRED. M. SMITH, M.D. (Chicago)
First Lieutenant, M. C., U. S. Army
JEFFERSON BARRACKS, MO.

In an attempt to discover if there is any method of diagnosing the so-called neurocirculatory asthenia before the men enter service, we have been engaged in an intensive study of the syndrome. We feel that the work has gone far enough to justify us in presenting our results briefly, leaving the more detailed statistics for later presentation. Our purpose is to state our reasons for considering that we can detect these cases at the recruiting depots or at the Local Examining Boards and thus save both applicant and government time and money.

Careful study of the reports of Lewis[1] and his associates leads us to believe that we are not dealing with the same class of patients. His patients were invalided from the front, where overexertion and shell shock were factors. Our patients have come from civil life, where men have been doing their daily tasks under no great strain. He was able to return 20 per cent. to active duty. Our experience coincides with that of Major Robey,[2] who found that these men were not benefited by graded exercises. These men, for the most part, had been working daily at some vocation. The work was uniform, required no sudden strain, no sudden call on the reserve of the heart. Frequently men told us that they themselves had found certain work too hard and had voluntarily sought easier and, at times, sedentary, jobs. This distinction, we consider, is important.

We have studied 435 cases. Two hundred of these were referred for examination at Camp Upton and Camp Beauregard (F. M. S.). The 235 cases that both of us have studied more in detail at Jefferson Barracks will, for the most part, form the basis of this report. These represent the referred cases at the recruit depot among 20,000 examinations during the months of July and August.

HISTORY

The careful history from the man who has tachycardia is almost the most important factor in the determination of a man's fitness for the Army. The men who have shortness of breath, a feeling of exhaustion out of all proportion to the exertion made, palpitation of the heart, precordial pain and dizziness on exertion in civil life have invariably failed in their military training. The 200 patients that were examined by one of us at Camp Upton and Camp Beauregard were men who had broken down in training. With very few exceptions, they complained of subjective symptoms that dated back into civil life, in some instances as far back as childhood.

Our plan has been to enter all patients into the hospital for observation who could not be rejected at once in the examining barracks. Patients with frank exophthalmic goiter, of evident hyperthyroidism and of patent pulmonary tuberculosis were rejected at once. The cases studied represent the men who were not normal, who had tachycardia and who, we considered, had not enough symptoms and signs to reject at once. One hundred and five patients have been put in hospital and been given graded exercise. The time in the hospital varies from four days to three weeks. Sixty-five have been discharged as unfit, all of whom had symptoms prior to the time they were drafted. Eighteen have been accepted for military service, all of whom had no subjective symptoms on exercise. These men were observed because of tachycardia.

ETIOLOGY

The irritable heart is frequently a symptom of some well recognized disease. In the study of 235 cases from the standpoint of etiology, the diagnosis of pulmonary tuberculosis was made in eighty-eight. In no instance was the opinion of one man taken as final. Frequently, the diagnosis was made on the basis of the findings of three or four examiners. Forty-one of the most doubtful cases were observed in the hospital. Here, these patients were given graded exercises, the temperature was taken every three hours, and frequent chest examinations were made. Roentgenograms were made in a number of cases, and were often of considerable value. The exercise caused a rise of temperature and brought out positive chest findings in cases which, previous to exercise, were only suspicious.

Seventy-three patients were discharged with the diagnosis of hyperthyroidism.[3] In all these, there were definite eye signs, as lagging of the lids, poor convergence and occasionally exophthalmos. The thyroid gland was enlarged in every instance. There was a tremor of the hand and tachycardia. The systolic blood pressure was usually increased, ranging from 120 to 170 mm. of mercury.

In thirty cases that gave a typical history of "effort syndrome," nothing was found to account for the condition. Twenty-one of these patients were rejected in the examining barracks with the diagnosis of irritable heart without hospital observation. On the basis of our later results, we feel that, possibly, tuberculosis could have been found in some of these men, had they been put under observation.

Three men had the symptoms and physical findings of early cirrhosis of the liver. One had chronic malaria, one bronchial asthma, and twenty-one are still in hospital under observation.

Eighteen men were sent to duty. These were men who had been sent to the hospital because of tachycardia, and had at no time subjective symptoms. They all responded to exercise well and, so far as we know, are having no difficulty in their training.

GRADED EXERCISES

The graded exercises have proved very valuable, first, in the determination of a man's fitness for the Army, and second, in establishing the diagnosis.

Those individuals who are not able to do the simplest exercises without distress and who have shown no improvement from day to day are very obviously not fit for military service. Those men who have given a history of having had subjective symptoms in civil life have all made complaints following these exercises. Those cases in which the irritable heart had as its basis pulmonary tuberculosis have usually responded poorest to the exercises.

[1] Lewis, Thomas: Report, Medical Research Committee, London, 1918.

[2] Robey, W. H., Jr., and Boas, E. P.: Neurocirculatory Asthenia, The Journal A. M. A., Aug. 17, 1918, p. 525.

[3] We have called these cases hyperthyroidism. We ourselves are not satisfied with the term. We feel that exophthalmic goiter would probably be a better term to use as all the cases were potentially Graves' disease. The term is in such general use that we have here employed it to designate cases not frankly exophthalmic goiter, but with certain of the Graves' disease stigmata.

In forty-one cases, we feel confident that the exercises brought out positive findings in the chest and caused a rise in temperature, so that we were justified in making the diagnosis of pulmonary tuberculosis. Thirteen of the patients under observation were discharged with the diagnosis of hyperthyroidism. The exercises in those cases brought out signs that previously were only suggestive.

SUMMARY

For the present, we feel safe in saying it is possible to detect the irritable heart before a man is inducted into service. This can be done, first, by taking a careful history, paying particular attention to previous attacks of dizziness or fainting, exhaustion, precordial pain, and pounding of the heart on *slight exertion;* second, by noting the unusual physical response to the hopping exercise and the increase in the pulse rate out of all proportion to the exercise.

THE INFLUENZA EPIDEMIC AT CAMP DIX, N. J.

MARTIN J. SYNNOTT, A.M., M.D. (Montclair, N. J.)
Major, M. C., U. S. Army; Chief of Medical Service
AND
ELBERT CLARK, Ph.D., M.D. (Chicago)
Major, M. C., U. S. Army; Chief of Laboratory Service
CAMP DIX, WRIGHTSTOWN, N. J.

The influenza epidemic began at Camp Dix, September 15, and ended, October 6. The number of daily admissions increased rapidly and reached the maximum, September 26, on which day 806 patients were received, making a total of 4,025 in the hospital on that date. The number then decreased daily, reaching the normal average of eighty admissions, October 7. During the twenty-two days of the epidemic, 6,500 patients were cared for. Approximately 6,000 of these men had influenza. There have been 800 deaths due to the epidemic. Four of our nurses and one dietitian died during the epidemic, contracting the disease while on duty. One medical officer was taken ill while on leave and died from bronchopneumonia a few days later at the Massachusetts General Hospital.

When the epidemic began to subside and the hospital discharges to increase, wards were consolidated as rapidly as possible. The emptied wards were renovated and disinfected thoroughly and all bedding sterilized in the steam autoclave before being used again for noninfluenza patients.

ADMINISTRATION

To take care of the large number of patients, all of the forty-eight wards of the hospital, except six, were turned over to the medical service; but in spite of this, it was found necessary to expand, and an annex was started in the camp. Through the cooperation of the headquarters authorities and the camp surgeon, a number of empty barracks were quickly equipped, a medical and nursing staff organized, and in this way eighteen additional wards with accommodations for 1,100 patients were provided. The annex was used for the most part for convalescent patients, and the patients were moved there from the base hospital as rapidly as safety permitted. Our rule was not to transfer patients until the temperature had been normal for forty-eight hours. They were kept in bed at the annex for another forty-eight hours and not discharged until the temperature had been normal for ten days.

By this plan overcrowding was avoided and, as soon as possible, arrangements were made by which each influenza and pneumonia patient in the hospital was given 100 square feet of floor space. All patients, including those on the porches, were placed in cubicles. Nurses, medical officers and orderlies wore gauze mouth and nose coverings while on duty. Nasal discharges and sputum of patients were disinfected. A 2 per cent. solution of tincture of iodin in physiologic sodium chlorid solution was used for oral and nasal hygiene. Floors of all wards were gone over daily with a cloth wet in disinfectant. Individual drinking cups were provided. Particular care was given to the disinfection of thermometers and other utensils as they passed from patient to patient. Enlisted attendants in wards wore white cotton coats and trousers. Medical officers and nurses were instructed to disinfect carefully their hands before and after the handling or examining of patients and before leaving the ward, or passing from one class of patients to another. Pails containing a disinfecting solution were provided at convenient places in every ward.

Blankets, mattresses, mattress covers and pillows were disinfected by steam before being used for another patient. Soiled linen was immersed in a 2 per cent. dilution of liquor formaldehydi before being sent to the laundry. The clothing of patients was disinfected by steam or formaldehyd before discharge.

For patients too ill to use covered sputum cups, paper napkins were provided for the reception of sputum and nasal secretions. At the head or side of each bed a paper bag was fastened with a pin or adhesive plaster. These bags were used for napkins, gauze, swabs and other infected refuse and burned when full.

The medical service was directed by the medical chief and an assistant. There were ten ward supervisors, admitting officers and consultants. These men met with the chief for a conference at 8 a. m. daily, when the work of the day was outlined and discussed. There was a daily conference of all medical officers attached to the medical service (about eighty-five officers at the time of maximum stress) at 1:15 p. m. when matters requiring advice, questions of discipline, treatment, etc., were gone into fully.

The patients were grouped as rapidly as possible, all uncomplicated influenza cases being kept together, and the cases complicated by pneumonia gathered in separate wards.

The following laboratory tests were ordered for all pneumonia patients:

1. Routine urine examination.
2. Urine precipitin test, for type of pneumococcus.
3. Blood examination: white corpuscle and differential blood count.
4. Blood culture (only in serious cases).
5. Sputum: Collected in sterile Petri dish, after patient had rinsed mouth and throat with physiologic sodium chlorid solution, to eliminate contaminating organisms as much as possible; for smear and white mouse necropsy to determine the type of pneumococcus.

The following rules are laid down for the guidance of ward surgeons in the general management of convalescent pneumonia patients:

1. It is advisable that in all serious or severely toxic cases of pneumonia, the patient shall remain in bed for at least two weeks after temperature is normal.
2. Convalescent patients are to be transferred to the convalescent ward, as soon as this can be safely done.
3. No patient will be transferred without the approval of the consultant. Patients so transferred will be carried on litters, not wheel chairs.
4. Before discharge from the hospital, all pneumonia patients are to be sent to the roentgen-ray laboratory for fluoroscopic heart examination and cardiac measurement.
5. Generally speaking, no patient is to be discharged until the heart is normal in size, as determined by fluoroscopic measurement.
6. No influenza patient is to be returned to duty until the temperature has been normal for ten days.

All ward surgeons were repeatedly warned to be on the alert for the early detection of empyema and were given these instructions:

1. Consult your supervisor as to advisability of exploration.
2. Technic of Exploration: A 10 to 20 c.c. Lüer syringe and appropriate needle. One per cent. cocain anesthesia by infiltration at site of puncture. Send fluid to laboratory (in syringe in which fluid is obtained) for smear and culture labeled "Chest fluid for smear and culture."
3. Roentgen ray to be requested as indicated.
4. Aspiration: If exploration has been advised and if fluid is sterile, do not remove by aspiration until after consultation and unless something in clinical condition warrants it, i. e., exacerbation of fever, pressure symptoms, respiratory distress, etc.
5. Repeated explorations are to be avoided on account of danger of conveying fresh infection from lung to pleura incident to puncture of lung by exploring needle. The pleural fluid may be sterile. Avoid infecting it.
6. If fluid is thin enough to run through a Potain aspirating outfit, it should be removed in this way, as often as symptoms indicate. If after consultation a case is considered to be one requiring thoracotomy, the sick soldier will be transferred to the surgical ward for operation.

In addition to the large stationary outfit in the roentgen-ray laboratory, we have two portable bedside machines. These were kept almost constantly in use during the epidemic.

CLINICAL FEATURES

The usual history was one of gradual onset with prodomes for four or five days prior to admission—consisting of headache, malaise, backache, myalgia, fever and chills or chilly sensations, and marked prostration. There was a history of anorexia, and of aggravation of symptoms, after drill or exercise. Occasionally the onset was sudden, sharp and severe. On admission there was cough, often with rusty sputum, a temperature of 103 F., occasionally hyperpyrexia, respirations of 28 or 30, the pulse between 80 and 120. A low temperature in a severe case was an unfavorable sign. The blood count showed usually leukopenia. The urine contained albumin and casts. The patients looked very ill, but often did not feel so. Few complained of sore throat or the early sticking pains in the chest, aggravated by coughing, so commonly observed in beginning pneumonia.

One third of our cases presented frank signs of pneumonia. Every patient who had fever, prostration, rapid pulse, increased respirations, cough and bloody sputum was at once put down as a pneumonia suspect, which diagnosis could usually be confirmed later by physical signs and roentgen examination.

Frequently no physical signs of pneumonia were apparent on the initial examination. A day or two later bronchopneumonia was discovered, the lobules subsequently tending to become confluent. This condition sometimes gave the physical signs of a lobar pneumonia, but the real condition was repeatedly demonstrated at necropsy. The roentgen ray was an invaluable aid in the diagnosis of such cases.

The outstanding feature of the disease was the extreme toxemia noted in the serious cases. We could predict almost from the first inspection the outcome of each case. There has been a sharp line of demarcation between the serious and mild cases. In the former, many patients developed a cyanosis early in the disease and died promptly, after periods varying from a few hours to three days after admission.

The cyanosis appeared early and was progressive. It was a fairly constant and characteristic symptom in the severe cases. This intense cyanosis was a striking phenomenon. The lips, ears, nose, cheeks, tongue, conjunctivae, fingers and sometimes the entire body partook of a dusky, leaden hue. Frequently this cyanosis was apparent before there were any demonstrable physical signs of pneumonia. The cause could not be ascertained, a few spectroscopic readings failing to show absorption bands of methemoglobin. As necropsy revealed marked so-called compensatory emphysema in these cases, and as cyanosis is a common accompaniment of emphysema, possibly this was in some way accountable for the condition. Otherwise a purely mechanical conception of the mode of production of the cyanosis seems untenable. Lividity, occurring early in the disease proved to be an ill omen.

Very often this cyanosis came on suddenly in patients who had been doing well. It was not due to cardiac dilatation. The pulse was often slow, full and regular in such cases, and remained so, with a rate under 100, almost until death.

The disparity between temperature and pulse was striking. Patients with temperature between 104 and 106 not infrequently had a pulse rate below 80. This we regard as a strong point in differential diagnosis between these influenzal pneumonias and those of pure pneumococcic origin.

The disease was a veritable plague. The extraordinary toxicity, the marked prostration, the extreme cyanosis and the rapidity of development stamp this disease as a distinct clinical entity heretofore not fully described.

It is entirely different from our previous pneumonia epidemics. It is fair to state that it is primarily a profound, rapidly progressing septicemia and toxemia in which pneumonia is an important but somewhat secondary factor.

There was noted in many instances a distinct tendency to relapse. In several of our mild cases, after a day or two of nearly normal temperature, exacerbations occurred and the infection changed to the severe, toxic type.

Herpes labialis was relatively infrequent, but became more common as the disease advanced. It was seemingly of little help in prognosis, as many with herpes died, contrary to the teachings of the older clinicians.

The sputum showed varying characteristics. It was mucoid, mucopurulent, blood streaked, frothy and bloody, the blood pure as in infarct.

In one of our cases it was thin, brown, without froth and homogeneous (prune juice variety). At times it was rusty but lacking tenaciousness and of the consistency of typically pneumonic sputum; it was odorless. In one case the patient coughed up a large quantity of homogeneous, thick, purulent, greenish sputum at one time.

Necropsy in this instance revealed multiple bronchopleural fistulas leading to an encapsulated empyema on the right side.

Tachypnea was constant and variable in rate. The expiratory grunt was uncommon.

The cough differed materially from that of lobar pneumonia, being free, often painless, sometimes paroxysmal, resembling the cough of pertussis. One may reason from this that pleurisy was relatively uncommon as an initial feature. Pleuritic rubs were occasionally heard, however, while diaphragmatic pleurisy with its referred pain was not uncommon, often simulating a condition suggestive of appendicitis.

Flushing of the face was common. An early generalized erythema resembling that of scarlatina, most noticeable on the chest and back, was often observed. Miliaria (sudamina) was common later in the disease, especially in lethal cases in which sweating was frequent and excessive.

The throat was usually injected, but not painful; the tonsils were not swollen as a rule; there was marked conjunctival congestion at the outset of the disease. The tongue was variable: usually coated, moist in milder cases, dry, cracked and occasionally bleeding in severe cases. Sordes appeared frequently on the teeth.

Hoarseness was frequent, due either to the trauma of coughing or to superficial laryngeal ulceration or edema, as demonstrated at necropsy.

The mental condition was either apathetic or there was an active delirium. Cerebration was slow at the onset; the sensorium was numb; a noticeable incident in attempting to elicit history was the frequent apparent disregard of one's question or a response with an interrogatory and blank "What?" or "Sir?" Possibly this was due to a defect of ratiocination, rather than a faulty sense perception (tubotympanic catarrh with retracted membrana tympani or straight lethargy). The patient's assurances and statements as to the condition in many instances were unreliable, a moribund patient stating that he felt very well, requesting permission to get out of bed, reading the daily newspaper in some instances audibly and intelligently, or laying plans optimistically for the future. In other cases, apprehensiveness was most striking, the patient fearing for the future, predicting in a gruesome way the time of death, and making requests to be carried out posthumously. In moribund patients, motor and psychic restlessness was remarkable. In some cases the typical typhoid state existed: stupor, low muttering delirium, subsultus, tendinum, carphology, incontinence of urine and feces; one patient lay for several days stupid with the eyes wide open following imaginary objects about the ward (coma vigil).

In the lungs, the physical signs varied from impairment of resonance, especially over the lower lobes, with diminution of the vesicular murmur; with showers of crepitant and later subcrepitant râles to straightforward signs of consolidation, namely, dulness, bronchial breath and voice, increased fremitus and whisper with a few consonating râles. Often the only evidences of early pneumonia were the signs first enumerated and these confined to a small area or a number of small areas, most commonly at the upper part of the right lower lobe or in either axilla, high up.

In the abdomen, meteorism occurred in some cases; in certain lethal cases it was excessive. Abdominal pain and tenderness were frequent, possibly not entirely due to pleurisy, but in the light of necropsy findings, to infection and hemorrhages in the rectus muscles. In one case necropsy revealed the presence of bilateral abscess in the lower rectus (Zenger's hyaline degeneration). The liver percussed large but was not often felt, owing to abdominal resistance. The spleen could be felt at or just below the costal margin in about one third of our cases. This finding was of little value, however, as many of these subjects were of the status lymphaticus type, in which cases splenomegaly is often observed.

Weakness and tremulousness of the extremities were noticeable manifestations in many cases.

Among accidents of the disease may be noted one case of death shortly after admission with no forewarning, and one case of sudden death many days after febrile period when the patient was regarded on the high road to convalescence.

EMPYEMA

There have been fewer cases of empyema in this epidemic than might be expected, owing to the fact of the extreme toxicity of the disease with the result that death has occurred early. Most of the cases examined postmortem showed lesions in the pleura which would undoubtedly have resulted in empyema had the patients lived longer. Twenty cases of frank empyema have been discovered up to the present time.

Our experience here has taught us that early operation is not advisable in empyema. Aspiration with the Potain apparatus is resorted to when fluid is demonstrated to be present in the pleural cavity, unless the fluid is found to be sterile, in which event it is not removed. Aspiration may be repeated at two to four day intervals. Many patients do well under this plan of treatment; and if a costectomy is later deemed advisable, the patient's chances of recovery are very much enhanced if this operation is delayed until the acute stage of the disease has been passed, and the patient has begun to immunize himself.

The following type case illustrates the wisdom of this procedure:

Col. F. D. L., taken ill while in New York, Sept. 21, 1918, had a severe chill the next day at 3 a. m. He traveled back to Mount Holly in the afternoon. He complained of fever, chilliness and drowsiness. Signs of a diffuse bronchopneumonia with involvement of all lobes quickly developed. On the fourth day there was a remission in temperature and the patient felt better, but on the fifth day he had an exacerbation and the condition rapidly became critical. His fever was continuously high and expectoration was bloody. There were several attacks of hematemesis and one rather severe hemoptysis. The patient became delirious, September 28. This condition persisted one week. He was cyanosed and toxic, with signs of dilatation of the right ventricle and myocardial failure. The pulse rate ranged between 140 and 150, with respirations between 44 and 50 a minute. A pronounced jaundice, due probably to a hemolytic infectious process, developed about this time. On the fifteenth day, signs of fluid developed at the base of the right chest. Exploration in the eighth interspace at the posterior axillary line revealed a cloudy serofibrinous exudate, which on smear and culture showed the staphylococcus. Next day, 250 c.c. were removed by aspiration. On the eighteenth day, 400 c.c. of slightly cloudy serous fluid were removed, and on the twentieth day 600 c.c. of frankly purulent fluid were obtained. On the twenty-third day, 1,120 c.c. of similar fluid were removed by aspiration. After this aspiration the patient's condition began to improve at once, and at present writing his temperature is normal, and the prognosis for recovery is excellent. The sputum on white mouse necropsy showed the Type IV pneumococcus. The urine contained albumin and casts. Cultures of the blood were made twice but were negative on each occasion. All aspirated fluid has shown a pure culture of *Staphylococcus aureus.*

OTHER COMPLICATIONS

The complications other than empyema associated with the epidemic were those ordinarily encountered in an infectious disease of great virulence. Pulmonary edema was a comparatively frequent terminal condition. One of the most striking of the complications was hemorrhage from the mucous membranes, especially from the nose, stomach and intestine. Frequently pneumonia patients would have hemoptysis like the hemorrhage of tuberculosis. Bleeding from the ears, and petechial hemorrhages in the skin also occurred. Purpura was seen rather frequently. Other complications were phlebitis, thrombosis, or embolism of peripheral arteries (with gangrene of the foot in two cases), toxic erythema, vomiting, diarrhea, conjunctivitis, convulsions, purulent peritonitis, inflammation of the accessory sinuses and of the middle ear, and pericardial effusion. A pronounced jaundice, not obstructive, as the stools are not acholic and probably of infectious origin, was noted in many of our severe cases. Retention of urine was not uncommon.

In several instances the infection produced a pronounced hemolytic effect with rapidly progressive anemia. In one instance, that of a medical officer, the red cell count was reduced to 1,600,000, with 50 per cent. hemoglobin on the fifth day of his disease. This patient is recovering.

A report of our series of cases, twenty in all, showing subcutaneous emphysema of the tissues of the neck, face, upper portion of the chest and arm will be published elsewhere.

Other rarer complications were meningismus, fibrinous and serofibrinous pleurisy, rupture of an encapsulated empyema into the bronchus, thyroiditis, pneumothorax and cerebral thrombosis or embolism (one case showed hemiparesis, hemianesthesia, and probably hemianopia).

TREATMENT

Influenza cases were treated symptomatically. Codein or heroin was found useful in relieving the distressing cough. Medicated steam vapor inhalations were found useful in relieving laryngeal irritation.

In the pneumonia cases, digitalis is begun early and given in full dose for forty-eight hours. It is then discontinued or reduced to one or two doses daily, after the heart muscle is digitalized.

Abdominal distention is guarded against, and when symptoms of this condition develop, an enema is given or, if necessary, pituitary solution hypodermically is administered.

If the patient is toxic or unable to take fluid freely by mouth, water is given by proctoclysis, hypodermoclysis or intravenous administration.

In the pulmonary edema cases, postural treatment, the Trendelenburg position being employed, was found useful in a few instances; in others it seemed to add to the distress. Atropin or belladonna did not prove of any value in these cases.

The diet that we have recommended for influenza and pneumonia cases is a nourishing one providing calories in excess of 3,000 a day. It includes such articles as gruels, broths, purées, eggs, and milk fortified with cream and lactose.

To lessen the danger of relapses and exacerbations, we believe it is of the utmost importance to keep all patients in bed until the temperature has been absolutely normal for at least forty-eight hours. The rule not to discharge patients until the temperature has been normal for ten days has been rigidly enforced.

SERUM THERAPY

Serum was administered in cases in which the laboratory reported the Type I pneumococcus. It was given only after desensitization and under the direction of the medical officer to whom the supervision of pneumonia patients had been entrusted. It was administered intravenously in doses of from 60 to 100 c.c. at twelve hour intervals until the temperature remained below 101 F.

SPINAL PUNCTURE

As many soldiers who died from pneumonia were shown at necropsy to have had an infection of the meninges with the pneumococcus organism, in a few instances of Type I, a lumbar puncture was advised in every case in which any symptoms of meningeal irritation developed. The spinal canal was drained, and the fluid withdrawn was sent to the laboratory for examination.

The precipitin test on the spinal fluid is rapidly done and the type thus easily determined. If the laboratory reported the Type I pneumococcus, serum was administered at once intraspinally (20 c.c.) and a desensitizing dose of 5 c.c. given subcutaneously. Five hours later, from 80 to 100 c.c. were given intravenously.

PROPHYLACTIC IMMUNIZATION

In the course of the epidemic the War Department offered prophylactic immunization to the camp, and several thousand inoculations have been given. These are given only to volunteers, but all medical officers, nurses, orderlies and soldiers in good health are strongly advised to take it. The vaccine consists of 10,000 million of each of the three types I, II and III of the pneumococcus. The dead organisms are suspended in cottonseed oil, making thus a lipovaccine. One dose is administered. The advantage claimed for oil over saline is that the vaccine is more slowly absorbed and hence the period of "negative phase," with lowered resistance, is avoided. Our experience at this camp substantiates this claim. All reactions have been light.

Observations following the use of this vaccine at Camp Upton indicate not only successful immunization against pneumococci of Types I, II and III, but also a very low incidence of streptococcus cases among the vaccinated. The vaccine is given subcutaneously.

Pneumonia is the most serious complication, and if this can be avoided, influenza will be robbed of most of its terrors.

PATHOLOGY AND BACTERIOLOGY

The pathology of the cases of influenzal pneumonia coming to necropsy at Camp Dix have presented very diverse pictures. In the cases that we have seen at necropsy the lesions were confined for the most part to the chest cavity. This is especially true of the cases which ran a rapidly fatal course. In the latter, the greater part of the visible pathologic changes consisted of very much congested and hemorrhagic, water-logged lungs. Some of the patients who had been in the hospital two weeks or longer presented a pathologic picture more or less like those bronchopneumonia patients coming to necropsy here last spring and those described by MacCallum for the pneumonia epidemic at Fort Sam Houston, Texas, during the winter of 1917-1918. Between these two extremes there have been many intermediate stages.

A notable feature of the cases in which death occurred early in the disease has been the extreme water-logged appearance of the lungs—lungs that are more or less completely filled and distended with a watery, bloody and frothy fluid, with petechial and larger hemorrhagic areas in the pleura. The right lung in one of our cases weighed just short of 4½ pounds and was absolutely devoid of air except for a small area at the apex of the upper lobe and small areas here and there along the anterior margin. The latter areas appeared to contain air under pressure. The remainder of the lung was tightly filled with fluid, was soft at all points, and did not contain any nodules or firmly consolidated areas. When the lung was held up, large quantities of fluid ran out. A slice cut from the lung lost about half its weight in fluid squeezed out by pressure with the hand. From this lung there was grown a nonhemolytic streptococcus and the influenza bacillus. Pronounced inflammation of the trachea and bronchi was noted in all cases in which death occurred early in the disease.

While only one case of well marked empyema has come to necropsy, several showed evidence of beginning empyema.

The heart showed nothing beyond dilatation of the right ventricle in the more acute cases. Early pericarditis has been seen in cases of longer duration.

The spleen as a rule showed no evident change.

The liver has weighed on the average approximately 2,000 gm. and has been more or less congested and yellowish.

The kidneys have shown a markedly congested and yellowish cortex.

The intestinal tract has shown in the majority of cases only slight congestion, and petechial hemorrhages in the gastric mucosa.

Blood examination in more than 700 cases has revealed in most instances an absence of leukocytosis in the more severe cases and during the acute stage of those running a more favorable course. The average has been about 5,000 white cells per cubic millimeter during the acute stage. The lowest recorded was 1,200.

The lymphocytes experienced a relative percentage increase. The red cell count has as a rule shown no decrease and frequently a high count during the acute stage. After two or three weeks in the hospital the picture changes in most of the serious cases. The red cell count decreases, sometimes to 1,600,000, and a leukocytosis develops ranging from 12,000 to 30,000 white cells, with polymorphonuclear leukocytes running as high as 95 per cent. So far as we have seen, the hemoglobin varies directly with the red cell count.

The urine in practically all seriously ill patients has shown a liberal amount of albumin with frequent casts.

BACTERIOLOGY

A large variety of organisms has been encountered in cultures and smears from the lung substance, from the bronchial mucous membrane and from the sputum. Streptococci and pneumococci have been most frequently found. The influenza bacillus (Pfeiffer's) has been encountered in sputum, bronchi and lungs, but we have made no particular effort to study it or to determine its frequency. It has, however, been encountered in the majority of cases when looked for. It has been recovered from the lung substance, from the bronchi, from the trachea and from the sputum, but in none of our large series (over 300) of blood cultures.

It is worthy of note that *Bacillus influenzae* has in no single instance been the sole invading organism. It has occurred, as stated, in the sputum and in secretions taken directly from the trachea and bronchi and from the lung, but it has never been in pure culture. It has been always associated with one or more pathogenic organisms. We have found it associated with *Micrococcus catharrhalis,* with the pneumococcus of various types, with *Streptococcus hemolyticus* or *viridans,* with pneumococci and streptococci, and in one or more of these combinations plus various other undetermined organisms. Of the latter class there have been observed; spirilla, gram-negative cocci and bacilli and frequently a pleomorphic gram-positive coccus. It would thus appear that, whatever rôle *Bacillus influenzae* plays in the present epidemic, it does not invade the blood and in all probability cannot solely be responsible for the fatal termination.

The sputum in more than 500 cases has been examined as to organisms and subjected to test for pneumococcus type by the white mouse necropsy method. The organisms mentioned above have been recovered, namely, pneumococci of various types, *Streptococcus viridans* and *hemolyticus, Micrococcus catharrhalis, Bacillus influenzae,* a gram-positive pleomorphic coccus, and gram-negative bacilli and cocci in the associations already noted. During the early phase of the epidemic when the pneumococcus was encountered, it as a rule failed to give any type reaction by either the precipitin or the agglutinin test. More recently Type III and to a less extent Type II pneumoccoci became more and more frequent.

Three hundred and fifty urines and 120 spinal fluids from seriously ill patients were subjected to the precipitin test. The results are comparable to those from the sputum examination, Types III and II became more frequent during the later phase of the epidemic. It would thus appear that neither pathologically nor bacteriologically are we dealing with a definite disease. There is a variety of conditions found at necropsy and a multiplicity of organisms in the various cases. The epidemic has, however, shown phases, the later of which tend to resemble the bronchopneumonia of streptococcus and pneumococcus origin.

CONCLUSIONS

We are of the opinion that the infection begins in the upper respiratory tract and is characterized by an intense exudative inflammation. A tracheitis and intense general bronchitis follow. The exudate in the severe cases is so thin and voluminous that neither coughing nor the ciliated epithelia suffice to throw it off. The lungs soon become water-logged. This exudate carries with it into the lungs the organisms ordinarily found in the nose, nasopharynx and throat, namely, streptococcus, Type IV pneumococcus, *M. catarrhalis,* Pfeiffer's bacillus, etc. A confluent lobular pneumonia ensues, caused by one or more of these organisms. In other words, we consider this a type of aspiration pneumonia.

However, it is by no means certain that *Bacillus influenzae* of Pfeiffer is the original infecting organism. We have not found it in pure culture in any of our cases examined postmortem. The disease may eventually be shown to be caused by some filterable virus or ultramicroscopic organism.

LOBAR PNEUMONIA AT A BASE HOSPITAL

LABORATORY AND CLINICAL STUDY OF FIFTY CASES *

LEON S. MEDALIA, M.D. (Boston)
Major, M. C., U. S. Army; Chief of Laboratory Service

AND

NATHAN S. SCHIFF, M.D. (New York)
First Lieutenant, M. C., U. S. Army

CAMP MACARTHUR, WACO, TEXAS

Early in March, 1918, it was suggested by one of us (L. S. M.) that a more careful study be made on the lobar pneumonia cases that appeared at this camp. The chief of the medical service was therefore requested to continue Lieutenant Schiff on duty as ward surgeon in charge of the pneumonia wards. It was felt that a comparative study of the cases clinically could best be made if the same man were continued on duty.

This article is a report on two series of cases. In the first, thirty cases were followed up in a routine way. Polyvalent antipneumococcus serum was administered in each case without regard to the outcome of the type determination. The second series is a study of twenty cases in which more complete laboratory methods were done, such as blood cultures, daily leukocyte counts, type determination, and the use therapeutically of Type I serum only in those cases that were found to be due to the Type I pneumococcus.

TABLE 1.—FREQUENCY OF POSITIVE BLOOD CULTURES IN PNEUMONIA AND ITS PROGNOSTIC SIGNIFICANCE (SECOND SERIES)

	Cases Examined		Blood Cultures				Mortality in Cases with			
			Positive		Negative		Positive Blood Cul.		Negative Blood Cul.	
Type	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.	No.	Per Cent.
I	3	15	1	33	2	66	—	—	—	—
II	9	45	4	44	5	56	1	25	—	—
III	—	—	—	—	—	—	—	—	—	—
IV	8	40	3	38	5	63	1	33	—	—

PNEUMOCOCCUS SEPTICEMIA AND ITS PROGNOSTIC SIGNIFICANCE

The incidence of positive blood cultures in lobar pneumonia has been variously stated as ranging from 20 to 50 per cent. The findings at the Rockefeller Institute[1] were 30 per cent. Our findings, as will be seen in Table 1, are 40 per cent., thus distributed: Type I, 33 per cent; Type II, 44 per cent., and Type IV, 38 per cent. The two deaths that occurred were both among those with the positive blood findings, one in Type II and the other in Type IV. The mortality of those with positive blood findings according to this table is 20 per cent., as compared with no mortality in the negative cases.

The technic followed was to obtain about 20 c.c. of blood from a vein at the elbow under aseptic precautions; plant 10 c.c. of the blood in a bottle containing 80 c.c. of meat infusion broth, and from 2 to 3 c.c. in each of a tube containing plain agar melted and brought down to 45 C., and plated. The cultures were kept under observation for from five to seven days and examined daily before a definite negative report was made. The typing was done mostly by Avery's cultural method. Both the agglutination and precipitin tests (the routine method was the agglutination test) were done in a number of cases. The mouse method was not used, owing to the impossibility of obtaining white mice.

TABLE 2.—COMPLICATIONS AND MORTALITY *

Type	No. Cases 1st Series	No. Cases 2d Series	Empyema 1st Series	Empyema 2d Series	Otitis 1st Series	Otitis 2d Series	Died 1st Series	Died 2d Series	Recovered 1st Series	Recovered 2d Series
I.........	3	3	0	1	0	0	0	0	3	3
II.........	4	9	0	2	0	3	0	1	4	8
III........	0	0	0	0	0	0	0	0	0	0
IV........	11	8	0	1	1	0	0	1	11	7
Undetermined...	12	0	0	0	0	0	0	0	12	0

* Comparison between Series 1, cases treated at random with polyvalent serum, and Series 2, those treated with Type I serum only when found due to Type I pneumococcus infection.

The pneumococcus obtained from the blood was in all cases found to correspond to the type obtained in the sputum.

The blood cultures were taken from two to nine days following the first initial symptoms, and in most cases from two to five days prior to the occurrence of the crisis.

It is significant that in the fifty cases here reported there was not a single case of Type III. It would be of interest to know whether the infection with this type of pneumococcus was as rare in other camps. In the thirty-one cases of lobar pneumonia reported by Cole and MacCallum[2] at Fort Sam Houston, Texas, they found only one case with Type III, or 3 per cent., as against 13 per cent. at the Rockefeller Institute.[1]

In a recent article by A. A. Small[3] in a report on the pneumonia cases at Camp Pike, the type determination findings were: Type I, 21 per cent.; Type II, 34 per cent.; Type IV, 45 per cent.—no Type III in the whole series. Our findings of those fifty cases that were typed were: Type I, 16 per cent.; Type II, 34 per cent.; Type IV, 50 per cent.—none of Type III in this series.

COMPARISON OF COMPLICATIONS AND MORTALITY BETWEEN THE TWO SERIES

In comparing the complications and mortality between the two series in Table 2, one cannot help but recognize the marked difference between them. One would expect the course of the disease to be much more severe and the mortality much higher in the first series of the thirty cases, which extended through the months of January, February and March, the coldest months of the year, as compared with the second series of cases, which extended through the last week of March, April and May, the wards and general treatment being the same and carried out by the same ward surgeon.

---

*From the Clinical and Pathological Laboratory, Base Hospital, Camp MacArthur, Waco, Texas.

[2] Cole, Rufus, and MacCallum, W. G.: Pneumonia at a Base Hospital, The Journal A. M. A., April 20, 1918, pp. 1146-1156.

[3] Small, A. A.: Pneumonia at a Base Hospital, The Journal A. M. A., Aug. 31, 1918, pp. 700-702.

As a matter of fact, the course of the disease was much worse in the second series of twenty cases, which had in its favor the better weather conditions, having four empyema cases, three cases with otitis media, and two deaths; while in the first series of thirty cases there were no empyema cases, only one with otitis media, and not a single death. The only difference in the treatment between the two series was the use of the polyvalent antipneumococcus serum as a routine measure in the first series, while only in those that were of Type I infection, three cases out of the twenty, in the second series was serum given. The general impression as expressed by Major O. H. Campbell, chief of the medical service, was to the effect that the cases in which the polyvalent serum was administered ran a much milder course, the patients feeling better, breathing easier, and in every respect being much better off than those patients in the second series who did not receive serum, not having Type I infection.

The same impression was expressed by the various ward surgeons who observed the other cases that occurred in camp on whom polyvalent serum was used as a routine measure. Credit for the use of the polyvalent serum is due to Major Campbell, who instituted its use as a routine measure in all cases of pneumonia in the beginning, before we had any facilities in the hospital to do type determination. Because of the apparent good the polyvalent serum did and the easier course these cases ran and the low mortality obtained, the routine use of polyvalent serum was continued for a long time after the type determination was instituted in this laboratory.

SPECIFIC THERAPY: POLYVALENT VERSUS TYPE I SERUM

A critical analysis of Table 2, with special reference to the difference in complications and mortality between the first series, which received the polyvalent serum as a routine measure, and the second, which did not, is the strongest evidence, at least for the present, that we have in favor of using the polyvalent serum as a routine measure. We have no means of determining thus far the amount of antibodies Type IV organisms are capable of producing against their own respective types, while against Type II, according to the Rockefeller Institute,[1] an antiserum can be produced, though much less potent than against Type I. These facts, and the fact that Type II plus Type IV infections make up from 70 to 80 per cent. of the cases of lobar pneumonia that occurred in the camps, strongly suggest the advisability of using the polyvalent serum as a routine measure, until such time at least as monovalent serums can be produced against the respective individual types of infections. The potency against Type I infection of the polyvalent antiserum, as pointed out by *Wayson and McCoy*[4] of the U. S. Public Health Service, must in all respects compare favorably with that of Type I monovalent antiserum.

The important thing in the use of an antiserum as a routine measure is the avoidance of anaphylaxis. This may be accomplished by the intradermal and subcutaneous test. The technic as followed in this hospital is the administration intradermally, on the flexor surface of the upper arm, of 0.5 c.c. of a 1 per cent. antipneumococcus serum in sterile saline, controlled by 0.5 c.c. of saline solution introduced at points from 3 to 4 cm. apart on the same level of the skin, followed, if negative, in fifteen minutes by 1 c.c. of straight serum subcutaneously. If the subcutaneous test is found negative, it is followed one hour later by 50 c.c. of polyvalent serum intravenously. This dose is repeated from every twelve to twenty-four hours until the temperature, respiration and pulse warrant its discontinuation.

If properly carried out, this intradermal and subcutaneous skin test should do away with the objection raised against the routine use of the polyvalent antipneumococcus serum of unquestionable potency (as tested by the U. S. Public Health Service) in pneumonia due to pneumococcus infections of whatever type.

TOXIC GASES IN MODERN WARFARE

WITH SPECIAL REFERENCE TO DIAGNOSIS AND TREATMENT

GEORGE WILLIAM NORRIS, M.D. (Philadelphia)
Lieutenant-Colonel, M. C., N. A.
FRANCE

The idea of employing gases in warfare is, of course, not new. In 360 B. C., the time of the Trojans, resinous woods, sulphur and pitch were employed. Long ago the Chinese availed themselves of the so-called "stink-pots" to choke and nauseate their adversaries. The Turks used "Greek fire" against the crusaders. In more modern times we find General Joubert protesting to General White, during the Anglo-Boer War, because the bursting lyddite shells caused suffocation. In the latter instance the carbon monoxid poisoning was, of course, entirely incidental to combustion and not primarily a method of destruction.

Under the guise of studying industrial intoxications, the Hun had experimented extensively with chlorin, bromin, formaldehyd, nitrous vapor, sulphurous anhydrid, etc., long before the beginning of the present war. The knowledge and experience thus gained was first employed in warfare in April, 1915, when large quantities of cylinder gas were discharged against the Canadians and Turcos at Ypres with such ghastly effect.

Since that time various gases, either simply or in combination, have been employed, nearly all of them being based, so far as their production is concerned, on chlorin or methyl alcohol. Lately, arsenical compounds have also been used.

METHODS OF EMPLOYMENT

1. Cylinder, drift or cloud gas (generally chlorin or phosgen). The gas is discharged from large numbers of big cylinders, generally at night or in the early morning when a steady, properly directed wind, of from 4 to 12 miles an hour, is blowing. The gas is heavier than air, sinks into trenches, dugouts and shell holes, and is unaffected by mist, rain or water courses. Such attacks have been made on a 5-mile front and have produced intoxication at points 6 miles behind the line.

2. Artillery shells. Shells containing gas in a liquid state, and lately also explosive charges to insure dissemination are used for distant ranges. With fifty or more guns firing ten shots a minute, often in salvos,

---

[4] Wayson, N. E., and McCoy, G. W.: The Potency of Antipneumococcic Serum, The Journal A. M. A., June 8, 1918, pp. 1747-1749.

it is quite possible to drench thoroughly a given area with gas, especially if the ground is low or wooded. Such shelling is now much in vogue previous to an infantry attack, and is often directed against artillery positions.

3. Mortars (short range projectors, "minenwerfer"). By this method enormous gas shells can be projected for 2,000 yards. A large number of mortars are fired simultaneously, by an electric device, and thus a tremendous concentration of gas may be attained in a given locality, practically without warning. After such attacks, 40 per cent. of casualties with 15 per cent. of fatalities are not uncommon. When one reflects that an 8-inch shell contains 2½ gallons of volatile liquid, it is not difficult to understand why this should be so.

4. Hand grenades. Grenades containing lacrimatory, combustible or lethal gas are occasionally employed to "clean out" saps and dugouts.

The effects of gas depends on: (1) the kind used, and the concentration obtained; (2) the duration of the exposure, and (3) the promptness and efficiency of protective measures, such as gas alarms and respirators. It should be borne in mind that symptoms may be delayed, sometimes for hours, in certain types of gases.

THE DIFFERENT TYPES OF GASES

1. Lacrimators (acetone, xylene or benzene bromid). These gases act immediately, causing a copious ocular irritation, intense lacrimation and thus a temporary, indirect functional blindness. They are commonly employed in gas chambers for purposes of instruction, and to test out the "fit" of a mask.

2. Sternutators (diphenylchlorarsin). The symptoms produced by this type of gas are immediate sneezing, coughing, headache, salivation, vomiting and substernal pain. They are employed preliminary to or early in a gas attack so as to render gas mask protection difficult or impossible. A man who is seized with the above mentioned symptoms generally finds it impossible to get or keep his mask on, and hence falls a victim to the lethal gas that accompanies or follows the initial dose.

3. Lung irritants (suffocating gases—chlorin, phosgen, diphosgen, oxychlorcarbon). These gases produce death by irritation of the pulmonary alveoli, resulting in edema of the lungs.

4. Vesicants (dichlorethylsulphid, dichlormethylether). The brunt of the attack is borne by the skin, eyes and upper respiratory tract. Blistering and subsequent sloughing of the tissues affected results in cutaneous burns and intense bronchial, tracheal and laryngeal inflammation, and sloughing. Death results from bronchopneumonia.

5. Gases destroying erythrocytic function. (*a*) Carbon monoxid—causing death by asphyxia resulting from methemoglobinemia.

(*b*) Arsin—causing hemolysis, jaundice, hemoglobinemia, nephritis and gastro-intestinal disturbances.

SPECIAL TYPES OR VARIETIES OF GAS

Diphosgen (trimethylchloroforminate, "surpalite"), —This gas, now used instead of phosgen ("palite"), is the most intense lung irritant known. In a dilution of 1 : 50 (rare) one inhalation kills by laryngeal spasm. It diffuses quickly, and in a dilution of 1 : 1,000,000 is toxic if breathed for a considerable time. When brought into contact with water it forms hydrochloric acid. It produces but little local or early irritation, and during periods of excitement or when mixed with smoke, may be breathed for some time without discomfort. It does, however, cause slight, early, ocular smarting, nausea, retching and vomiting (pharyngeal irritation). Its chief and important action, however, is on the pulmonary alveoli, and its effect is pulmonary edema.

Symptoms: These are slight cough, nausea, substernal pain, soreness or sense of constriction, headache, epigastric pain, dyspnea, fever from 100 to 106, syncope and weakness.

Slightly gassed cases are difficult to diagnosticate. The symptoms may be slight and physical signs absent. It is safe to assume that a man who shows no physical signs at the end of from twenty-four to thirty-six hours either has not been gassed or, if so, only to a negligible degree.

The severe cases fall into one of two categories: (*a*) cyanotic cases: increasing restlessness, dyspnea, weakness and cough with slight frothy, sometimes blood-tinged, expectoration; dyspnea, cyanosis, venous distention and a full, strong pulse of about 100; or (*b*) gray cases: slight cough, no expectoration, ashen pallor, marked tachypnea, shallow respiration, a leaky skin, very low blood pressure, a rapid, thready pulse (140) and collapse. Needless to say, the prognosis in the latter case is far worse than in the former.

Physical Signs: In the early stages there may be no auscultatory signs—simply an increase of the respiratory rate and an increased fulness of the pulse. Later the signs of beginning pulmonary edema manifest themselves—crackling râles, harsh breath sounds, not infrequently together with pleural frictions. It is noteworthy and striking that such physical findings are first noted, most marked, and, during convalescence, most persistent, over the upper lobes anteriorly, and not, as is the case in disease, at the bases. Local tympany may be found, resulting from emphysematous areas. As the edema increases, resonance becomes impaired and breath sounds are lost, being totally replaced by crackling râles or completely silent areas. The heart dulness increases to the right, and as dilatation increases, the pulmonic second sound becomes enfeebled. Death results from deficient oxygenation due to cardiac dilatation, following pulmonary engorgement and edema. It is mechanical, therefore, there being no direct cardiotoxic effect. Occasionally symptoms and physical signs may be precipitated by physical exertion or a full meal, several hours after the exposure to gas, the patient collapsing quite suddenly.

Morbid Anatomy: The trachea and bronchi are filled with slightly blood-tinged froth. The lungs outwardly appear mottled as a result of alternating areas of congestion and emphysema. On section, congestion, capillary hemorrhages and extreme, widespread edema are found. Small, slightly bloody, pleural effusions are quite common. The right heart is dilated and often contains thrombi. The venous system is engorged, and thromboses are sometimes encountered. The kidneys are congested, and the glomeruli may contain clots.

Four fifths of all the deaths occur within the first twenty-four hours. If the patient can be tided over this interval he usually recovers. The pulmonary edema clears up rapidly after the second or third day. Cardiac dilatation may persist and be troublesome for several weeks.

Treatment: This consists of: (1) absolute rest; (2) warmth (to prevent shivering, which increases carbon dioxid); (3) venesection; (4) removal of clothing; (5) oxygen inhalations (in the cyanotic cases); (6) cardiac stimulation (camphor, digitalin, spartein, caffein), and (7) fresh air.

Venesection is the sheet anchor of treatment. About 500 c.c. of blood should be removed as soon as evidences of pulmonary edema begin to appear. This may have to be repeated within a few hours. The beneficial effects, both subjective and objective, are immediate and striking. A good-sized vein must be freely opened or a portion of its wall excised, since the blood is inspissated, clots quickly and flows with difficulty. Most observers believe that in cases belonging to the ashen gray type the patients should not be bled.

Contraindications in Treatment: Opium in any form, ipecac, emetin, expectorants or depressants, such as acetylsalicylic acid or other coal tar derivatives, are contraindicated. Opium tends to check cough, and hence the patient drowns in his own secretions sooner than he otherwise would.

Atropin produces no beneficial results; neither does epinephrin. It should be remembered that recovery may occur in the most desperate cases; active treatment should be kept up as long as the patient breathes. Raising the foot of the bed sometimes aids expectoration.

Practical Considerations: Gassed patients usually arrive in large numbers and tend to swamp the personnel of the field hospital; hence to save time and labor the following arrangements should be made:

1. Serious cases should be kept in one or two wards, and not scattered at random. Thus both observation and treatment will be facilitated.
2. One officer is detailed to see all incoming cases, to judge of their severity and order their disposition. He should circulate constantly through the wards so as to pick out cases with beginning edema.
3. One officer and one or two orderlies are assigned to perform venesection in the severe cases. More may be required.
4. One officer should supervise the oxygen administration and the giving of hypodermic stimulation. Oxygen is given for five or ten minutes, with ten or fifteen-minute intervals, according to the degree of cyanosis present.

All diphosgen patients must be transported by litter. They are not allowed to undress or bathe themselves. Light food in small quantities is allowed in the milder cases. In the severe cases the patients are kept at the field hospital for several days until acute symptoms have subsided. It the evacuation hospital it is usually possible at the end of a few days to pick out the patients who will soon be fit for duty from those requiring evacuation to the base. Convalescence will be more prolonged and must be more guarded than in the case of yperite ("mustard gas").

Chlorin.—The treatment of chlorin poisoning is similar in all respects to that of diphosgen, except that ammonia inhalations may be added.

Dichlorethylsulphid (yperite, "mustard gas").—This gas has a faint odor which has been compared to French-mustard, vinegar, etc. Characteristically, it produces no immediate or early effects. One may remain or sleep in a dugout charged with it for several hours before becoming conscious of its presence, and then it is often too late.

Occasionally nausea, retching, vomiting, and smarting of the eyes occur as valuable, even life-saving, symptoms at the end of from twenty to sixty minutes. As a rule, however, symptoms appear from two to five hours after the beginning of exposure.

The face and neck become red and the eyelids swollen. There is marked photophobia and blepharospasm, lacrimation, ocular and substernal and epigastric pain, pharyngitis, bronchitis, and an increased pulse and respiratory rate. At the end of twenty-four hours, severely gassed patients show in addition to an exaggeration of the symptoms just mentioned, cutaneous blistering of the face, neck, scrotum, inner surface of thighs, penis, buttocks, etc. Burns in the latter region are especially common after sitting on gas-impregnated earth. Widespread and severe purulent inflammation of all the upper mucosae and the bronchi are present. The expectoration consists of bloody pus and is sometimes accompanied by sloughs of the entire tracheal and bronchial mucous membrane.

At the end of forty-eight hours, bronchopneumonia, often widespread and coalescing, has occurred, as a result of tissue destruction and leukopenia. The patient is delirious, coughs, is cyanotic, exhausted, tortured by pain and suffocation, and finally lapses into unconsciousness. It is to be noted that in contrast to the phosgen cases, dyspnea, cyanosis, fever, tachycardia and prostration occur late. Practically none of the patients die within thirty-six hours, and death may occur weeks later. Slight transient albuminuria is quite common.

Convalescence: Photophobia of a functional type and unexplained origin persists for weeks and should be ignored as soon as local inflammatory changes have subsided. Bronchitis may also last for weeks, together with substernal and epigastric pain. None of these symptoms should prevent a man's being sent to the convalescent depot if his general physical condition warrants it. Some of the cases develop E. S. (effort syndrome), and require special treatment in "heart classes." Severely gassed patients—those that have developed a demonstrable bronchopneumonia—usually die. The slightly gassed patients usually recover. There is doubtless a middle class in which bronchiectasis develops in time as a result of cicatricial changes; but so far as is known, true tuberculosis as a sequel does not occur. It is, of course, easy to conceive that latent lesions may be activated by gassing.

Morbid Anatomy: There are purulent inflammation, destruction and sloughing of the respiratory mucosae. The lungs show alternating areas of congestion, emphysema and bronchopneumonia. The small bronchi and bronchioles are filled with pus. Sometimes coalescing areas of bronchopneumonia may produce extensive lobar involvement. Small areas of pulmonary edema may exist. The stomach, chiefly near the cardia, as well as the duodenum, generally contains submucous hemorrhages, conditions apparently resulting from the swallowing of saliva and responsible for the epigastric pain and gastro-intestinal symptoms. The kidneys are usually congested. Death results from bronchopneumonia and asphyxia due to obstruction of the smaller bronchi and bronchioles by mucosal sloughs and pus.

Treatment: 1. The patient should be evacuated early; as soon as possible, all clothes should be removed and the entire body washed with soap and water. (Yperite is freely soluble in animal and vegetable fats.) The hair, which retains the gas, should be clipped. The room must be well ventilated, the clothes thrown outdoors, and the attendants must wear gloves.

2. The eyes, nose and mouth should be douched with 1 per cent sodium bicarbonate solution. This should be followed by the instillation of a bland oil. If obtainable, 0.5 per cent. dichloramin-T dissolved in chlorcosane should be used for the eyes (1 drop in 3, each eye, thrice daily as suggested by Major J. E. Sweet). Dichloramin-T has a twofold purpose: (*a*) It is a chemical antidote, by virtue of its chlorin. (*b*) It is an antiseptic.

3. Skin burns are treated with any alkaline dusting powder (talc, magnesium carbonate, zinc oxid), or by oily dressings such as petrolatum or paraffin. They are not as painful as fire burns, presumably owing to the edema and degeneration of the nerve endings (Warthin and Weller). Blisters should be pricked, but their fluid should not be allowed to run over neighboring skin areas.

DIFFERENTIAL DIAGNOSIS AND TREATMENT

Yperite (mustard gas):	Diphosgen (also phosgen and chlorin):
Late symptoms; death from three to sixty days after exposure.	Early symptoms, death from one minute to forty-eight hours after exposure.
Skin burns, conjunctivitis, bronchitis, bronchopneumonia.	No skin burns nor conjunctivitis; dyspnea, cyanosis, edema of lungs.
Late fever, weakness, dyspnea and tachycardia.	Early fever, weakness and tachycardia.
Remove clothes, wash with *soap*, cut hair, treat eyes and skin burns.	Absolute rest, *venesection*, oxygen and cardiac stimulants.
Codein or morphin indicated for severe cough.	Codein and morphin contraindicated.
After-effects: photophobia, *bronchitis*, aphonia.	*After-effects:* weakness and cardiac dilatation.

4. Cough is treated with steam inhalations (benzoin), codein or morphin; and, unless the skin is already blistered, by counterirritation of the chest (mustard).

Eye shades should be provided, or light bandages applied. The latter must not prevent the free escape of discharges. Eye pain is relieved by forcing open the lids from time to time, and allowing the imprisoned secretions to escape. Cocain must not be used on account of its deleterious effect on the cornea. The ensuing purulent conjunctivitis, and occasional corneal ulceration, are treated by customary methods. The eyes rarely suffer permanent damage. Patients who have developed bronchopneumonia should be screened, to prevent, if possible, the infection of others. Oxygen inhalations are useful as a method of alleviation in severe cases, but they are not life saving as in the case of diphosgen, etc.

Clothing permeated with yperite if unaired remains poisonous for weeks. The gas can best be removed by passing the clothing through a steam sterilizer (thirty minutes wet steam, fifteen minutes dry steam, fifteen minutes air). If no sterilizer is available, they should be sunned and aired until they can be steamed.

Slightly gassed patients, of whom there are usually large numbers, may be allowed to walk to the shower baths and wash themselves. Physical exertion does not entail danger in any way comparable to that which exists after exposure to the phosgen group of gases.

Much diagnostic assistance may be gained by nonsuggestive questioning of the more intelligent and not too greatly prostrated patients. The patient should tell his own tale in regard to odors, irritation, nausea, vomiting, sneezing, cough or weakness. Early sneezing and headache point to sternutants or arsin; early cough, vomiting and weakness to phosgen; late conjunctivitis, nausea and cough, to yperite. Prognosis should never be discussed in the hearing of patients: psychoneuroses are too easily developed.

Ethyldichlorarsin.—This gas and others containing arsenic are now increasingly used. Lately a shell containing 50 per cent. dichlormethylether and 50 per cent. ethyldichlorarsin has been employed. Aside from early sneezing, it produces a condition practically identical with yperite except for the fact that its action is much more rapid. It is said that the arsenical gases, in addition to the other symptoms, produce somnolence, nephritis (edema of the hands and face), abdominal cramps, diarrhea and hemolytic jaundice. I have not as yet seen any such cases.

Carbon Monoxid.—This gas, which results from the combustion of high explosives, produces similar, though less intense, symptoms than the illuminating gas poisoning of civil life. Thus we find headache, asthenia, amnesia, delirium and syncope; symptoms which result from methemoglobinemia. Such cases are sometimes evacuated as "shock."

Treatment: This consists of rest, oxygen, stimulation and transfusion. Bleeding is, of course, contraindicated.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ANTIRABIC VACCINE (See N. N. R., 1918, p. 324).

Dr. D. L. Harris' Laboratory, St. Louis (National Pathological Laboratories, Chicago).

Rabies Vaccine (Harris).—Brains and spinal cords of rabbits, dead of fixed virus rabies infection, are ground to a paste which is frozen in a container surrounded with carbon dioxide snow. The mass is pulverized and rapidly dried *in vacuo*. The resulting dry powder is standardized by the method devised by Dr. Harris, and stored *in vacuo* in the cold. One dose is given daily over a period of ten days or more, the early doses increasing in unitage up to a maximum. Each package contains vaccine and apparatus for the administration of one complete treatment, consisting of 10 tubes of rabies vaccine (Harris), sealed in a vacuum, and numbered consecutively; 10 vials containing sodium chloride solution for preparing the vaccine solution; and a Lüer syringe with needle.

Drug Cultivation in Madras.—According to U. S. Consul Lucien Memminger at Madras, India, experiments are being made in the cultivation of a number of drug plants on the Nilgiri plantations. Among them are jalap, ipecacuanha, belladonna, foxglove, henbane, common mint, fennel and rosemary, as well as lobelia inflata and chenopodium. Jalap has been raised for a number of years. On account of its high price during the war efforts have been made with some success to increase the production on the government cinchona plantations and in botanic gardens. It has been found that the plant can be propagated from cuttings from the young stems as well as from the tubers, which latter is the usual method. In Ootacamund an acre of jalap yields about 5,000 pounds of green tubers, or about 1,000 pounds of powder.

THE NONIDENTITY OF ANTINEURITIC AND ANTISCORBUTIC FACTORS IN NUTRITION

When the investigations that resulted in the demonstration that beriberi is truly a disease due to dietary deficiency established the vitamin hypothesis, an impetus was at once given to the consideration of other conditions of malnutrition from the same general standpoint. Before long, scurvy, rickets, pellagra and other maladies were put into the category of dietary deficiency diseases. As the polishings of rice had been clearly demonstrated to contain a substance—a vitamin—which will prevent the onset of beriberi or cure its symptoms when once they have made their appearance, a multiplicity of specific vitamins was at once postulated, each involved in a definite disease. In rickets, and particularly in scurvy, the probability that a dietetic factor is concerned has long been recognized; and in many instances improvement or cure has followed the institution of changes in the regimen of the patients. The specificity of the dietary deficiency diseases lent probability to the existence of specific deficiencies and consequently to the existence of a multiplicity of essential vitamins.

Meanwhile the need has been demonstrated of at least two types of vitamins in addition to the familiar nutrients, if physiologic well-being is to be attained. Investigations[1] are tending to demonstrate that certain properties of the water-soluble food accessory are similar to those associated with the so-called antineuritic vitamin which prevents the onset of beriberi and cures experimental polyneuritis. In fact, the suggestion has already been advanced that they are identical. Hence the question at once suggests itself as to whether the other alleged vitamins are identical, rather than specific—in other words, whether the belief in a diversity of nutrition-promoting substances should be abandoned.

For at least two of these vitamin-like factors in nutrition, the answer to this query is a negative one. It has long been known that many plants and fruit juices are capable of preventing and curing scurvy, that is, they contain an antiscorbutic substance. The information as to the chemical and physical properties of the latter has been exceedingly meager—far more so than in the case of the antineuritic vitamin studied by Funk and others.[2] A recent investigation[3] at the Lister Institute, London, has led Harden and Zilva to the definite conclusion that the antiscorbutic property is not identical with the antineuritic factor, since substances showing marked antineuritic activity are antiscorbutically inactive, and vice versa. There is also evidence that the antiscorbutic substance is more thermolabile than the antineuritic. The latest experiments show that, under certain conditions at least, the antineuritic substance behaves quite differently from the other toward adsorbents. If a mixture is made of autolyzed yeast—containing antineuritic vitamin—and orange juice, a recognized antiscorbutic, fullers' earth will remove the antineuritic factor while the other property remains unaltered. Common adsorbents like fullers' earth and colloidal ferric hydroxid do not appreciably affect the antiscorbutic potency of orange juice, which, furthermore, can even be filtered through porcelain without having its activity vitiated to any appreciable extent. The nonidentity of the curative agents for two diseases associated with faulty nutrition raises the question whether each malady is actually due to an avitaminosis or lack of suitable vitamin in the diet — a recently debated problem.

THYROID FUNCTIONS AND THERAPY

There can be little doubt that some, at least, of the so-called endocrine glands play an important part in metabolism. An attempt at present, however, to discover their precise function on the basis of dependable facts is more than likely to lead into a maze of conflicting hypotheses, some of which will not bear even superficial scrutiny. Endocrinology, to borrow a pretentious designation, still remains in good part a collection of guesses enriched and in some cases confused by clinical experiences. It will be imperative to prepare a far more substantial foundation for these new aspects of physiology and pathology before the therapy of the subject can be put on a rational basis. Lately several substantial contributions in the direction of progress have been made. Carefully conducted experiments on thyroidectomized animals in which precautions were taken to leave the parathyroid glands functionally intact have shown that, following the abolition of thyroid function, there ensues an unmistakable hypoglycemia and also a tendency to delayed removal of glucose from the blood, that is, a delayed blood sugar tolerance curve.[1] An explanation is thus afforded for the low blood sugar values observed in myxedema and cretinism. Since hypoglycemia has been reported in Addison's disease, pituitary disorders and other less clearly defined endocrine conditions, such as muscular dystrophy,[2] it has been suggested that this symptom is evidence of hypofunction of the endocrine glands, the thyroid being taken as an example.[3] It seems likely, therefore, that as the thyroid evidently functions to maintain the blood sugar at its normal level, there is a very intimate relation between the gland and carbohydrate metabolism.

[3] Harden, A., and Zilva, S. S.: The Differential Behavior of the Antineuritic and Antiscorbutic Factors Toward Adsorbents, Biochem. Jour., 1918, **12**, 93.

With respect to nitrogenous metabolism, it has long been known that administration of thyroid preparations may stimulate the disintegration of tissue. In an attempt to trace the specific effect thus recorded to definite metabolic factors, Janney and Isaacson[4] have studied the partition of nitrogen in the urine both in hypothyroidal conditions and after experimental hyperthyroidism. For the latter purpose Kendall's thyroid hormone was administered. No selective action of the thyroid on urea and ammonia could be observed; their percentages remained within normal limits. The creatinin metabolism also appeared to be independent of thyroid influence. The purin metabolism alone seemed to be altered, the output being decreased in hypothyroid function and increased in hyperthyroid conditions. In a special series of investigations at the Montefiore Home and Hospital, New York,[5] it was found that the nitrogen balance is a rather delicate measure of the action of thyroid products. Contrary to widely held assumptions, a gain rather than a loss of nitrogen is a result of the therapeutic action of the thyroid; whereas a loss of nitrogen, that is, of protein, is due to the toxic action of the gland.

If it proves to be correct that nitrogen loss following thyroid medication is a toxic manifestation —a sign of overdosage or hyperthyroidism—a fact of unique importance will have been acquired. Janney fortifies his belief by reminding us that abolition of thyroid function in the very young leads to stunted growth (cretinism). Proper thyroid medication causes growth to be resumed. The therapeutic action of the thyroid should therefore be found to be accompanied by a gain, not a loss, of nitrogen. Accordingly, small doses of thyroid which suffice to cause clinical improvement in a cretin have actually been attended by an increased retention of nitrogen in the body. According to Janney's interpretation, the depressed nitrogen excretion in cretinism is not due to "absence of stimulatory effect," but rather to the failure of normal repair and growth processes controlled by the thyroid. As these constructive processes are inhibited, little food is taken, because more cannot be assimilated. A low nitrogen output results.

That the metabolism is depressed in cretinism has long been recognized. Janney's studies indicate that this cannot be due to decreased alimentary absorption of food attributable to intestinal sluggishness. The adiposity sometimes observed may be due to the altered assimilability of sugar, since disturbances of carbohydrate metabolism have now been demonstrated to attend hypothyroid conditions. With these newer points of view, the problems of therapy and dosage can be considered to better advantage.

THE ILLINOIS EXPERIMENT IN REGULATING MEDICAL PRACTICE

Seventeen months have elapsed since the new arrangement became effective for regulating the practice of medicine in Illinois under the Consolidation Law. As already outlined in The Journal,[1] the registration of physicians, together with the licensing of dentists, pharmacists, midwives, followers of various cults and other registrable occupations, were together placed in a single department headed by an official who had authority to select advisers in the registration of each of the professions and occupations concerned. This arrangement in Illinois is an experiment, since it has no parallel in the methods adopted in other states. The arrangement places in a single department the control of all forms of healing, and the director of the department is in position to require, without discrimination, reasonable educational qualifications of all who are to practice regardless of the "system" or method of treatment employed. The success of any law depends, of course, on the ability and integrity of those appointed to enforce it. That the new law in Illinois is in proper hands is evident from the energetic prosecution of medical crooks and illegal practitioners since July 1, 1917, and in the establishing of better conditions in medical schools. The article by Mr. Francis W. Shepardson, director of the Department of Registration and Education of the State of Illinois, which was published two weeks ago,[2] therefore deserves careful reading. Mr. Shepardson and his co-workers entered on their duties with little or no knowledge of the irregularities of quacks, crooks and charlatans, who have always preyed on the sick and the injured. These irregularities, however, have been and are well known to the better class of physicians, who from time immemorial have struggled to uphold the dignity and honor of the medical profession—although Mr. Shepardson in his article apparently has not appreciated this fact. The article is written with the vividness usual to a layman who has suddenly had his eyes opened to the seriousness of the conditions disclosed. As he states:

---

[1] The Illinois Consolidation Bill Becomes a Law, The Journal A. M. A., March 17, 1917, p. 869.

[2] Shepardson, F. W.: A Registration Fee for Physicians, The Journal A. M. A., Nov. 16, 1918, p. 1629.

> They found an army of advertising charlatans, some with fixed offices and others appearing "for one day only," making extravagant claims of curative skill in handling all diseases, specialists in everything, blatant fakers, robbing the poor and the ignorant, preying on the superstitions of gullible foreigners, as bold and daring bandits as ever sandbagged a lone wayfarer at night.

The irregularities found, however, were not only of those who because they hold degrees in medicine are physicians, but who prefer to resort to quackery; the description includes, also, the hordes of those representing the endless variety of cults, fads and isms, who skulk in the shadow of the medical profession, but who excuse their failure to secure the educational qualifications required of physicians by the claim that they are "not practicing medicine." As Mr. Shepardson further states:

> They found a motley array of so-called "doctors" of every name and cult under the sun: regulars, homeopaths, eclectics, osteopaths, chiropractors, naprapaths, spondylotherapaths, mechanotherapaths, suggestive therapaths, psycotherapaths, naturotherapaths, iridologists, magnetic healers, religious healers, and many other varieties, the list forcibly reminding one of the description which Masson gives in his "Life of Milton" of the sects which flourished in England in the poet's time. After naming a great many, he includes in a sweeping classification the remainder of the some hundred-odd varieties of "fluent, rancorous, inquisitorial and on the whole nasty kinds of Christians."

This article is especially interesting because it turns the strong light of publicity on the quacks, cultists and pretenders who for ages have thrown discredit on the practice of medicine. It is well known to medical men that the conditions disclosed in Illinois are not limited to that state. A similar investigation would show affairs equally as bad or worse in other states. Only a few states have provided for regulating all forms of the practice of the healing art by a single department. On the other hand, as previously shown in The Journal,[3] the authority over the various forms of healing has been divided in several states (Arkansas, for example) among as many as six different and independent boards—a situation which allows faddists, quacks, medical crooks and charlatans to prey at will on the credulity of people who are rendered still more unwary in times of worry, sickness and distress. Mr. Shepardson's disclosures tend to show what is the next great reform movement needed in this country, namely, the conducting of a thorough investigation by a disinterested but competent committee of educators of the conditions underlying the practice of medicine in the United States, similar to that conducted by Mr. Justice Hodgins in Ontario two years ago. All the publicity possible should be given to the conditions found. The medical profession as a whole has nothing to fear from it and would undoubtedly favor such a house cleaning. It is only the quacks, crooks and fakers who prefer to skulk in the darkness and who, like rats, will try to hide when the light is turned on. The medical profession has striven for years to clear out these offenders, but the public has either remained indifferent or has unknowingly sided with the pretenders. The efforts of the profession have frequently been misinterpreted as being made in its own interests, and the cultists and quacks have claimed that they were being "persecuted by the medical trust," etc. It is evident, therefore, that the most effective investigation would be by an educational agency representing the public and independent of the medical profession. It is clear also that in each state the licensing of those who are to treat the sick should be in charge of a single board of disinterested but competent lay educators who, as in Illinois, are authorized to select an advisory board of physicians to aid in enforcing the practice laws. Finally, such educational qualifications should be required as will insure that those licensed shall have a knowledge of the normal functions of the human body and their reactions to injury and disease.

DOES BEER CONTAIN VITAMINS?

In the final appeals of the advocates of beer for a hearing in defense of their claims, considerable emphasis has been given to the nutrient properties of the brewed malt beverages. As cereals form the basis for the production of beer, the advertising specialist has hit on the clever device of calling this fluid "liquid bread." No cogent reason is given, however, why one should depart from the time honored custom of consuming bread prepared in the more substantial form of a nonalcoholic loaf.

The discovery that the dietetic value of a food product cannot be determined solely by reference to its calorific value or its content of long recognized nutrients has introduced new criteria into the study of nutrition. With the recognition of "quality" distinctions in proteins and the existence of vitamins has come the need of investigation from new and more numerous standards. It has become evident that articles intended for the dietary should be examined and evaluated not only for the usual ingredients, but also for the accessory factors which may add to their dietary significance.

The beer enthusiasts have been quick to grasp the situation. Barley[1] and yeast, both of which are involved in the manufacture of beer, are recognized sources of nutrition-promoting vitamin. It is true that the barley is germinated and heated to produce malt prior to the brewing process. The conjecture that vitamins may be present in beer is therefore not an unreasonable one. However, the popular alcoholic beverage is meeting its Waterloo on all sides. An investigation made by Harden and Zilva[2] to test the subject by the physiologic methods now available has given a clear-cut answer. Their conclusion is that bottled ale and stout, and fined beer as brought to the market, are lacking both in the antineuritic and antiscorbutic accessory factors, and kilned malt is also wanting in these two principles. It is an interesting commentary on the alcoholic aspects of the subject that in testing for the antineuritic factor by attempting to cure polyneuritic pigeons it was necessary to remove the alcohol from the beer, lest this component might induce the very disease which the postulated beer vitamin was expected to relieve or avert.

The truth is the same today as it has been for decades. Beer is not chiefly appreciated on account of the nutritious value of its ingredients, nor on account of the by-products of the brewing industry which may help to produce milk and meat. Beer and alcohol still go together; and the claims of alcohol for respectful consideration have been duly considered and found wanting.

Current Comment

THE ANTIQUITY OF DISEASE

The development of a new subdivision of science, paleopathology, which aims to interpret the pathologic conditions discovered among the fossil remains of ancient geologic times, is likely to throw new light on the antiquity of disease. Existing evidences already relegate its beginnings back as far as the carboniferous or great coal period. We may be certain, particularly as the result of the investigations of French scientists, that fungi and bacteria existed in this early period, although the presence of such micro-organisms does not constitute a convincing proof of their pathogenicity. According to Moodie,[3] who has reviewed much of the work in this field of study, the great Permian period, with its widespread development of curious reptilian forms, has furnished us with the first evidences of traumatic conditions as they prevailed among the early forms of life. Fractures may have occurred earlier than the Permian, but they have not yet been seen. Some of the uncovered fossil vertebrates have been described as exhibiting opisthotonos or spastic distress.[4] In other instances, necrosis of the bones has been postulated. Even such specific lesions as are represented by hemangiomas have been detected by microscopic study of the fossil remains of the great dinosaurs. Osteomas and other osseous defects are also known to have occurred. Dental caries is certainly not a novelty of modern ages. Moodie points out that no new ideas of pathology have beeen revealed by the study of the ancient lesions; but, he adds further, none were to be expected, since the organization of the animal forms of ancient times presumably differed only in minor details from the structures of the present geologic age. The presence of lesions suggests definite causes for their origin. Whether they represent extinct diseases or still existent etiologic factors remains to be ascertained as part of the development of the newly formulated science.

INDUSTRIAL MEDICINE IN THE PLACEMENT OF RETURNED SOLDIERS

As America entered the war, industry faced the tremendous problem of releasing millions of workmen, and, at the same time, maintaining or increasing production. Now that the war is over, it faces the no less difficult problem of assimilating the returned and disabled soldiers without seriously affecting production and labor conditions. Wisdom calls for the safe and efficient utilization of all workers, and it should guide the redistribution in industry of our returned soldiers. Most employers will welcome back those who left their jobs to enter the Army or Navy. Patriotism, fairness, generosity or whatever be the motive, the fact remains that scientific placement of these returned soldiers will be a wiser policy than their indiscriminate employment even in the industries from which they came. Eventually, the returned soldier, be he physically fit or physically disabled, will have to compete with his fellows for employment and wages on the basis of efficiency. Industry will be forced to use these men as it will have to use all workers—where they can be most productive. The returned soldiers in the aggregate will come back in better physical condition than when they left employment. Many of them will know what physical defects they possess and something of their significance. They will know that they can adapt themselves to new conditions of life and work. It will be for the good of all if industry, in reassimilating these men, capitalizes these changed conditions of body and mind by placement in the light of physical qualifications. Herein lies a great opportunity for the industrial physician and surgeon. He can carry over into the solution of a national problem his skill and experience in the human maintenance department of modern industry. As a physician he can take stock of a man's physical assets in relation to the work he can perform and, in cooperation with efficient employment managers, can place that man in his most advantageous occupation. But not all of our soldiers and sailors will come back physically fit. Some will return with physical capital much depleted. Some have been crippled or maimed or blinded. Some have been disabled by less apparent but no less serious injuries, such as shell shock and other war neuroses, disease, strain, exposure and other incidents of modern warfare. For these the government is making adequate provision for medical and surgical treatment, convalescent care, occupational therapy, vocational education and for placement in gainful employment. In carrying out this program, industrial physicians and surgeons have been given an important place. As these reconstructed men return to civilian life to become self-supporting members of society rather than pensioners, the industrial physician, by the nature of his calling, will be the wisest guide in their placement in industry and in the maintenance of their productive ability.

TERMINAL INFECTIONS

The reactions by which the organism defends itself against bacteria are by no means simple in nature. Despite the almost limitless opportunities for the introduction of the micro-organisms, they rarely reach the blood stream. This is due in part to mechanisms that prevent their passage through the exterior of the body, or devices that destroy them within the alimentary path. It is further due, however, to factors of immunity which are chemical in nature. Whenever bodily resistance of this sort is referred to we think of the so-called immunity reactions. Bacteriolysins, agglutinins, precipitins and opsonins play a prominent part in determining whether bacteria can be present or multiply in the blood. It is commonly believed that prior to death from other than very acute or accidental causes the natural defenses of the body may fail to a large extent. If this is true we may expect that invasion of the blood stream will be frequent, and consequently true terminal infections may be added to those already present as a primary cause of disease. The question here involved is capable of at least partial solution by actual examination of the blood—by investigation of bacteremias in the agonal period. This aspect of the bacterial invasion of the blood stream has been considered recently at the Magee Pathological Laboratories of the Mercy Hospital in Pittsburgh by Richey and Goehring,[1] who tried to determine the frequency of the presence of bacteria in the peripheral vessels immediately after death. This anatomic location was selected in preference to the heart as a source of the blood because of the relatively great postmortem invasion of the heart's blood from surrounding structures. Out of more than 200 cases, about one third gave positive cultures. The value of the method was fortified by the fact that when antemortem cultures were taken, the results were usually the same as those obtained by immediate postmortem examination through the median basilic or cephalic vein. In the acute traumatic deaths only one positive culture was obtained out of thirty-six examinations. This was in striking contrast to the thirty-six positive results out of fifty-five trials in the case of chronic debilitating diseases. Cocci appeared to be the commonest invaders of the blood stream, the representative of the streptococcus-pneumococcus group being most conspicuous. Pneumococci were isolated immediately after death in 50 per cent. of the cases diagnosed clinically as pneumonia. There can no longer be any doubt that true terminal infections frequently occur under the conditions of lowered resistance. Judging from the character of the organisms isolated, the main foci are probably in the intestine, the pulmonary alveoli, the upper respiratory passages, and other mucous membranes.

THE BACTERIA ON VEGETABLES

In the earlier days of modern bacteriologic technic there was developed a sort of semipopular scientific sport which might not inaptly have been termed "microbe hunting." Air, food and water, books and bankbills, toys and toggery were examined for evidences of bacteria. Danger seemed to lurk in everything that was acceptable to mankind, until the realization came that not all bacteria are baneful, and that some may even be beneficent. Thus it became the duty of the bacteriologist to identify our microbial enemies and direct his hygienic warfare more specifically against them. There are other lessons, too, that progress has taught. The unsuspected carrier has been brought into the limelight. In the dairy industry the importance of the cleanliness of the utensils used and of the personnel has become emphasized along with the necessity of keeping the milk-producing animal free from objectionable germs. Lately considerable has been said about the significance of sanitary conditions of food shops for the public health. In this connection a recent bacterial examination of green vegetables sold in Chicago stores is not without interest. At the University of Chicago, Kurk[1] attempted to discover whether the general sanitary condition of the store at which the purchase was made had any influence on the bacterial contents. *Bacillus coli* was found on twenty-two out of twenty-nine samples of the vegetables. It was present in ten out of twelve samples from stores classified as clean; in six out of ten samples from stores classed as fair, in five out of six from dirty stores and in watercress from a free lunch counter. Streptococci were found on three samples, two being from clean stores. Thus there was no indication that the general sanitary conditions of the store influenced the bacterial count. A clean shop is not a guarantee of hygienic safety; for food, like man, may be a carrier.

"SCIENTIFIC" NOMENCLATURE

A member of the Association's chemical laboratory, who is in the service, writes from a well-known eastern institution deploring the use of proprietary names around the laboratory there. He writes:

> In bacteriology we disinfect our hands with a solution labeled, "Lysol." I asked one of the instructors why they didn't use Liquor Cresolis Compositus. He replied that that actually was the substance in the bottle, but that it was labeled "Lysol" so the doctors would know what they wanted!

Comment on this would be gilding refined gold, and painting the lily.

Medical Mobilization and the War

Personnel of the Medical Department

On November 22 the total commissioned personnel of the Medical Corps was 31,158, a decrease of 240 from the previous week, consisting of 3 major-generals, 7 brigadier-generals, 187 colonels, 431 lieutenant-colonels, 2,338 majors, 9,807 captains and 18,385 first lieutenants. The total number in active service was 30,339, a decrease from the previous week of 252. To date 2,791 officers have been discharged for the following causes: physical disability, 1,006; inaptitude, 333; other branches of service, 727; resignations, 305; domestic troubles, 64; needed by community, 50; deaths, 261; dismissals, 24; duty completed, 3; no reasons given, 18.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Alabama

To Camp Custer, Mich., base hospital, for instruction, from Fort Oglethorpe, Major M. MASON, Birmingham.

To Camp Jackson, S. C., base hospital, for instruction, from Fort Oglethorpe, Capt. D. G. CAMPBELL, Mobile.

To Camp Sheridan, Ala., base hospital, from Fort Oglethorpe, Lieut. W. L. SHACKLEFORD, Gordo.

To Canal Zone, from Washington, Major G. H. S. SEARCY, Tuscaloosa.

To Cape May, N. J., base hospital, from Fort Sill, Lieut. C. H. DRAKE, Birmingham.

To Charleston, S. C., from Camp Beauregard, Capt. S. G. GAY, Selma.

To Fort Oglethorpe, evacuation hospital, from Camp Joseph E. Johnston, Lieut. J. R. CHISOLM, Marion Junction.

To Omaha, Neb., Creighton University, from Lincoln, Lieut. R. CALLEN, Birmingham.

To Port Clinton, Ohio, from Atlanta, Major W. C. DABNEY, Birmingham.

To Rockefeller Institute for instruction in the treatment of infected wounds, and on completion *to Camp Meade, Md.*, base hospital, from Fort Oglethorpe, Capt. J. H. ASHCRAFT, Fayette. On completion *to Camp Upton, N. Y.*, base hospital, from Fort Oglethorpe, Capt. F. P. PETTEY, Albany.

To St. Paul, Minn., Overland Bldg., from Fort Wayne, Mich., Capt. A. P. WEBB, Atmore.

Alaska

To Camp Meade, Md., base hospital, from Fort Oglethorpe, Capt. W. T. H. PALLISTER, Juneau.

Arizona

To Camp Sheridan, Ala., base hospital, from Fort Oglethorpe, Lieut. E. B. THOMPSON, Benson.

To Cape May, N. J., base hospital, from Walter Reed General Hospital, Capt. C. A. THOMAS, Tucson.

Arkansas

To Camp Colt, Pa., from Camp Custer, Lieut. W. M. MAJORS, Walcott.

To Camp Jackson, S. C., from Camp Custer, Lieut. W. M. MATTHEWS, Crossett.

To Camp Knox, Ky., from Fort Oglethorpe, Lieut. A. C. KOLB, Hope.

To Carlisle, Pa., from Plattsburg Barracks, Lieut. J. B. HESTERLY, Prescott.

To Cincinnati, Ohio, University of Cincinnati, from Camp Custer, Lieut. E. BAKER, Dermott.

To Fort Snelling, Minn., from Jefferson Barracks, Major W. K. READ, Texarkana.

California

To Army Medical School for instruction, from New Cumberland, Pa., Lieut. R. W. WILCOX, San Francisco.

To Boston, Mass., from Camp Custer, Capts. J. E. CLARK, Oakland; E. A. JONES, Taft.

To Camp Cody, N. M., base hospital, from Camp Kearney, Major H. C. LOOS, San Diego.

To Camp Crane, Pa., from Camp Kearney, Capt. E. H. THOMPSON, Burbank. Base hospital, from Fort Douglas, Capt. W. B. DEAS; from Camp Fremont, Capt. R. PATEK, San Francisco; from New York, Lieut. F. H. TAYLOR, San Diego. Evacuation hospital, from San Francisco, Capt. C. A. BELL, Santa Barbara. Mobile hospital, from Camp Kearney, Lieut. J. H. NORMAN, Allegheny. Surgical group, from Camp Kearney, Capt. J. C. ROBERTSON, Modesto.

To Camp Custer, Mich., base hospital, for instruction, from Fort Oglethorpe, Capt. H. L. PARISH, Oakland.

To Camp Jackson, S. C., from Camp Custer, Lieut. W. F. KELLER, Long Beach.

To Camp Kearney, Calif., Capt. C. H. WILDER, Oakland.

To Camp Kendrick, N. J., from Fort Sill, Lieut. G. F. HARRIS, San Diego.

To Camp Lewis, Wash., as orthopedic surgeon, from San Francisco, Capt. N. T. ENLOE, Chico; Lieut. D. R. WILSON, San Jose.

To Camp Sevier, S. C., as tuberculosis examiner, from New Haven, Major R. L. BYRNES, Los Angeles. Base hospital, from Fort McDowell, Col. P. C. FAUNTLEROY.

To Camp Shelby, Miss., base hospital, from Camp Fremont, Capt. T. R. McNAB, Los Angeles; from Camp Pike, Capt. G. J. BERGENER, San Francisco.

To Camp Upton, N. Y., base hospital, from Camp Wheeler, Lieut. H. D. WILLIAMS, San Francisco; from Fort Oglethorpe, Capt. J. C. COPELAND, Los Angeles.

To Camp Wheeler, Ga., base hospital, from Camp Kearney, Lieut. G. H. BOYD, Los Angeles; from Fort Oglethorpe, Capt. J. G. HAM, San Bernardino.

To Cape May, N. J., base hospital, from Camp Grant, Capt. C. A. JOHNSON, Los Angeles; from Rock Island Arsenal, Capt. F. F. SPRAGUE, Los Banos.

To Fort McHenry, Md., from Ann Arbor, Capt. B. P. STOOKEY, Los Angeles.

To Fort Sheridan, Ill., base hospital, from Camp Cody, Capt. W. H. SMITH, Los Angeles; from Camp Lewis, Capt. R. CADWALLADER, San Francisco.

To Mineola, N. Y., Hazelhurst Field, for instruction, from Fort Riley, Capt. V. D. BROWN, San Francisco.

To report to the commanding general, Southeastern Department, from North Charleston, Lieut. A. E. DICKINSON, San Jose.

To San Francisco, Calif., Leland Stanford University, for instruction, from Letterman General Hospital, Capts. W. C. BAKER, San Mateo; E. L. COTTRELL, Scotia; Lieut. L. DOZIER, Stockton. Letterman General Hospital, Major L. ELOESSER, San Francisco.

The following order has been revoked: *To Camp Crane, Pa.*, from San Francisco, Major A. C. CARLTON, San Mateo.

Canal Zone

To Camp Crane, Pa., mobile hospital, from New Haven, Lieut. D. J. MURPHY, Corozal.

To Fort Oglethorpe, evacuation hospital, from Camp Shelby, Lieut. L. M. DRENNAN, Ancon.

Colorado

To Azalea, N. C., from Markleton, Pa., Major P. A. LOOMIS, Colorado Springs.

To Camp Greene, N. C., base hospital, from Camp Logan, Major J. H. BROWN, Colorado Springs.

To Camp Knox, Ky., from Fort Oglethorpe, Lieut. P. C. GEISSLER, Colorado Springs.

To Camp Lee, Va., base hospital, from Fort Riley, Lieut. R. L. CHARLES, Denver.

To Camp Logan, Texas, base hospital, from Camp Shelby, Capt. T. A. STODDARD, Pueblo.

To Camp Sheridan, Montgomery, Ala., from Cedar Falls, Capt. J. A. DUNWODY, Cripple Creek.

To Camp Wadsworth, S. C., base hospital, from Fort Riley, Lieut. K. F. ROEHRIG, Denver.

To Fort Oglethorpe, evacuation hospital, from Camp Cody, Major H. S. FINNEY, Denver.

To Fort Sheridan, Ill., base hospital, from Fort Riley, Lieut. A. R. WILLIAMSON, Pueblo.

To Newport News, Va., from Rockefeller Institute, Capt. E. G. GRIFFIN, Denver.

To Urbana, Ill., University of Illinois, Lieut.-Col. C. N. BARNEY, Denver.

To Washington, D. C., from Fort Oglethorpe, Lieut. P. B. WALLACE, Eagle.

Connecticut

To Camp Abraham Eustis, Va., base hospital, from New Haven, Lieut. H. W. BRAYTON, Hartford.

To Camp Sevier, S. C., base hospital, from Camp Gordon, Capt. R. W. LOWE, Ridgefield.

To Camp Shelby, Miss., base hospital, from Fort Oglethorpe, Capt. F. F. SIMONTON, Thompsonville.

District of Columbia

To Camp Bowie, Texas, as division surgeon, Lieut.-Col. H. B. McINTYRE.

To Camp Crane, Pa., base hospital, from Lakewood, N. J., Lieut. F. D. ADAMS, Washington. Surgical group, from Walter Reed General Hospital, Lieut.-Col. F. B. LUND.

To Camp Devens, Mass., base hospital, from Fort Oglethorpe, Capt. P. E. LARKIN, Washington.

To Camp McClellan, Ala., as division surgeon, Lieut.-Col. A. W. SCHOENLEBER.

[illegible] from Walter Reed General Hospital, Lieut. H. F. [illegible]

[illegible] from Western Department, Lieut.-Col. W. P. BANTA.

Florida

To Army Medical School for instruction, from Newport News, Major J. W. ALSOBROOK, Plant City.

To Camp Crane, Pa., base hospital, from Fort Oglethorpe, Capt. D. FORSTER, Hawks Park; from Lakewood, N. J., Lieut. A. J. WOOD, St. Petersburg.

To Camp Sheridan, Ala., base hospital, from Camp Shelby, Capt. G. R. HOLDEN, Jacksonville.

To Charleston, S. C., from Camp Lee, Major G. R. PLUMMER, Key West.

To Fort Ethan Allen, Vt., base hospital, from Camp Devens, Capt. L. A. PEEK, West Palm Beach.

Georgia

To Atlanta, Ga., Morehouse College, and Atlanta University, from duty as a private, Lieut. R. B. FOSTER, Athens.

To Camp Colt, Pa., from Camp Upton, Lieut. C. A. WITMER, Waycross.

To Camp Crane, Pa., evacuation hospital, from Camp Jackson, Capt. W. B. CRAWFORD, Savannah.

To Camp Gordon, Ga., from Walter Reed General Hospital, Lieut. C. REED, Babcock.

To Camp Sherman, Ohio, sanitary train, from Fort Oglethorpe, Lieut.-Col. J. L. ROBINSON.

To Camp Wadsworth, S. C., base hospital, from Fort Oglethorpe, Lieut. J. G. DEVANE, Adel.

To San Antonio, Texas, Kelly Field, from Americus, Ga., Lieut. J. M. J. LIKE, Fitzgerald.

To White Plains, N. Y., for instruction, from Fort McPherson, Capt. G. P. HUGULEY, Atlanta.

Idaho

To Washington, D. C., for instruction, from Jefferson Barracks, Capt. R. E. MASON, Mackay.

Illinois

To Ann Arbor, Mich., University of Michigan, for instruction, from New York, Capt. O. T. ROBERG, Chicago.

To Austin, Texas, Texas State University, from Indianapolis, Major O. A. SUTTLE, Mount Vernon.

To Biltmore, N. C., from Camp Crane, Lieut. H. E. LUTYENS, Farmingdale.

To Boston, Mass., from Camp Custer, Lieut. H. D. EATON, Harvard.

To Camp Crane, Pa., evacuation hospital, from Camp Grant, Lieut. P. F. SNYDER, Chicago; from New York, Capt. H. A. BEAM, Moline. Mobile hospital, from New Haven, Lieut. P. B. RABENNECK, Nashville.

To Camp Custer, Mich., base hospital, for instruction, Capts. P. M. OLIVER, W. J. SWIFT, Chicago.

To Camp Forrest, Ga., to examine drafted men for nervous and mental diseases, from Fort Oglethorpe, Capt. I. J. FRISCH, Chicago.

To Camp Greene, N. C., from Fort Oglethorpe, Lieut. S. E. LYNCH, Chicago. Base hospital, from Camp Hancock, Lieut. E. H. SEIFERT, Chicago.

To Camp Hancock, Ga., base hospital, for instruction, from Fort Oglethorpe, Lieut. E. ZIMMERMAN, Quincy.

To Camp Jackson, S. C., from Camp Custer, Lieuts. J. J. LEACH, P. P. O'CONNOR, Chicago; J. R. BIERLY, Springfield.

To Camp Joseph E. Johnston, Fla., base hospital, for instruction, from Fort Oglethorpe, Capt. L. A. BEATON, Chicago; Lieut. E. AUSTIN, Benton.

To Camp Kendrick, N. J., from Camp Colt, Lieut. R. M. MONTFORT, Danville.

To Camp Logan, Texas, base hospital, from Fort Oglethorpe, Capt. T. H. PAGE, Peoria. Base hospital, for instruction, from Fort Oglethorpe, Lieut. H. H. FLETCHER, Winchester. *To examine drafted men* and on completion *to base hospital*, from Fort Oglethorpe, Capt. F. W. JONES, Alton.

To Camp MacArthur, Texas, base hospital, from Fort Oglethorpe, Lieut. G. T. MEACHAM, Taylorville.

To Camp McClellan, Ala., base hospital, from Camp Beauregard, Major T. O. WARD, Mount Vernon; from Fort Oglethorpe, Capt. J. K. RETICKER, Quincy.

To Camp Sevier, S. C., base hospital, from Fort Oglethorpe, Capt. L. A. BURHANS, Peoria.

To Camp Shelby, Miss., base hospital, from Camp Gordon, Capt. H. L. THOMPSON, Harrisburg.

To Camp Sheridan, Ala., from Fort Oglethorpe; Lieuts. G. W. WESTERMEIER, Carlinville; G. E. KNAPPENBERGER, Macomb. Base hospital, from Fort Oglethorpe, Capt. H. G. WRIGHT, DeKalb; Lieut. W. G. McCANDLESS, Sterling.

To Camp Travis, Texas, base hospital, for instruction, Lieut. G. HALPERIN, Chicago.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Meeting Deferred.—The officers of the Third District Medical Society have decided to postpone their meeting for this year on account of the disturbed condition of the profession.

Personal.—Dr. James W. Smith, who shot and killed his brother-in-law, Danny Shannon, October 16, was acquitted after four hours' deliberation, November 16, by a jury in Montgomery County, where the case was taken on a change of venue.——Dr. Robert B. Corney, Tucker, for three years penitentiary physician at the state farm, has resigned to enter the military service.

CALIFORNIA

Personal.—Dr. Manzanito B. Bolton, Quincy, has been appointed county physician of Plumas County.——Dr. Ralph L. Larsen, San Francisco, sustained a severe scalp wound and bruises in the overturning of his automobile near Rodeo.

Chinese Herb Man Sentenced.—Tom Shee Binn, whose activities as a practitioner in herbs without the formality of a drug license and who has been brought into police courts many times, is said to have been sentenced to a fine of $350 and to imprisonment for 180 days in jail, November 15. A part of the evidence in which the conviction was made was to the effect that he charged J. A. Dunn $780 for herbs to prevent Spanish influenza, and that Dunn, notwithstanding, died from the disease.

Ask That Physician Be Allowed to Remain.—November 15, the California State Board of Health telegraphed to the Surgeon-General of the Public Health Service protesting against the recall of the physicians attached to the service who were sent into the state to help combat influenza. It was said that conditions had not sufficiently improved to justify their withdrawal. There was general improvement, but a few communities were still asking for assistance. The total number of cases reported to the state board to the date mentioned was 146,023, and 1,761 cases were reported on that date. In San Francisco it was announced by the health officer that the situation would warrant the abolishment of the masks in about a week. There had been 23,409 cases in the city and 1,927 deaths.

COLORADO

Personal.—Dr. J. Wylie Jones, who has been in active service for more than a year and was seriously wounded, is now recovered and returned to duty.

Municipal Sanatorium for Denver.—A communication proposing a municipal sanatorium with a capacity of 100 beds, for Denver, was presented to the mayor and city council by the Denver Anti-Tuberculosis Society, November 12. The communication was referred to the committee on health for investigation. It states that there were in the city in 1917, 645 deaths from tuberculosis; 118 of these were contracted there, and that there were about 3,000 persons in Denver who were suffering from tuberculosis, who were financially unable to secure necessary treatment.

CONNECTICUT

Transfer Feebleminded.—Dr. Charles T. LaMoure, superintendent of the Mansfield State Training School and Hospital, has transferred to that institution the inmates of the former Connecticut School for Feeble-Minded at Lakeville.

State Society Meeting.—The eleventh semiannual meeting of the Connecticut State Medical Society was held at New London, October 3, in connection with the semiannual meeting of the New London County Medical Society. Among the subjects brought up for discussion were: Child Welfare Work and The Tuberculosis Problem in the Army.

Personal.—Dr. Louis J. Pons, Milford, has been appointed medical examiner (coroner) of New Haven County, to succeed Dr. William J. H. Fischer, Milford, who has entered the military service.——Dr. Julius G. Henry, New Haven, has been appointed city epidemiologist.——Dr. Arthur S. McQueen, Branford, has been appointed medical examiner (coroner) for the district, to succeed Dr. Charles W. Gaylord, deceased.

GEORGIA

Personal.—Dr. Lorick T. Pattilo, Moultrie, county health commissioner of Colquitt County, has resigned.

Legislation on Public Health Subjects.—At the last session of the legislature four important health measures were passed. Two of these relate to the prevention of venereal disease, one to the prevention of ophthalmia neonatorum and one to the establishment of sanatoriums for tuberculosis patients in small cities, and jointly by small cities and counties. The first law is entitled "An act to penalize those who solicit for the purpose of prostitution," etc., and makes it a misdemeanor to make any such solicitation by any means whatever or to convey by automobile or otherwise any person in connection with such solicitation. Any one convicted under the act who is operating an automobile or other conveyance for hire immediately forfeits his license for such conveyance, and no license to operate a public vehicle can thereafter be obtained. The second law names syphilis, gonorrhea and chancroid as venereal diseases, declares them infectious, communicable and dangerous to public health, and is entitled "an act relating to venereal diseases, to require the reporting of cases thereof, to penalize those who expose others to infection, to authorize the examination, treatment and isolation of persons infected therewith, to give the health authorities certain power over jails and prisons in connection therewith, to authorize the state board of health to promulgate rules and regulations relating thereto and to declare a penalty for the violation of the provisions of this act, or any rules or regulations prescribed thereunder or any rule or regulation passed and promulgated by the state board of health under the authority of this or any other act." Law No. 3 declares it a misdemeanor for any-person attending a new-born infant to fail to provide prophylactic treatment against gonorrheal infection. The law states that: "it shall be the duty of any person who shall be in attendance on any childbirth to apply to the child such prophylactic treatment as may be prescribed by the state board of health to prevent blindness from gonococcus infection, and that any person who shall nurse or attend any infant shall report any inflammation of the eyes of said child that shall develop within two weeks after birth to the local health officer or to a licensed physician." The law in reference to tuberculosis provides that: "Any cities in Georgia which have a population of not less than 15,000 inhabitants, or any cities of not less than 5,000 inhabitants located in a county which has a population of not less than 25,000 inhabitants, to establish and maintain, either alone or in connection with the county authorities of the county in which such city may be located, may jointly build sanatoriums for the treatment of this disease." The law was greatly needed to encourage the fight against tuberculosis in smaller cities as practically none of these now have means of treating tuberculosis patients locally. The management of the State Tuberculosis Sanatorium at Alto was given to the state board of health instead of to the board of managers originally constituted by the law establishing the institution.

INDIANA

Influenza.—November 20, it was announced that forty-two counties of the state had reported a total of 1,506 new cases of influenza, the largest number reported for twenty-four hours for two weeks. Among the cities reporting a recrudescence of the disease, in some of which the ban either had not been removed or was restored, were Gary, Greensburg, Brookville, Richmond, Logansport, Yorktown, Muncie and West Muncie, South Bend, Anderson, Fort Wayne, Columbia City, Bloomington, Terre Haute, Owensville, Bluffton, Goshen Berne, Wabash, Fairmount and Indianapolis. In a few places improvement is noted.

IOWA

County Election.—At the annual meeting of the Scott County Medical Association, held November 5, in Davenport, Dr. Roscoe P. Carney was elected president; Dr. Thomas D. Starbuch, vice president; Dr. Robert E. Jameson, secretary, and Dr. Sidney G. Hands, treasurer, all of Davenport.

Personal.—Dr. Elizabeth Speers-Gillette, Marshalltown, is reported to have been adjudged insane and committeed to the State Hospital at Independence.——Lieut. Milo O. Brush, Shenandoah, when about to sail for France, fell in New York fracturing his clavicle and is under treatment at the base hospital, Camp Upton.

KENTUCKY

Personal.—Dr. Louis W. Eckels, Jr., has been appointed medical inspector for the health department of Louisville.——J. C. Gilbert, Paducah, has been appointed a member of the state board of pharmacy, succeeding Dr. J. H. Martin, Winchester.

Senior Student Dies.—Kline V. Menefee, a senior student at Ohio-Miami Medical College, Cincinnati, aged 23, who had been working in Cincinnati during the recent epidemic of influenza, died at his home in Covington, November 4, from pneumonia, following influenza.

MARYLAND

Night Clinics at Hopkins.—Cooperating with medical officials of the United States government, night clinics have been inaugurated at the Johns Hopkins Hospital in the interest of social diseases. Tuesday and Thursday are set aside for women, and Wednesday and Friday for men.

Personal.—Dr. Homer E. Tabler, Hancock, is reported to be seriously ill with pneumonia.——At a meeting of the Hagerstown Medical Society, November 14, Dr. William D. Campbell, Hagerstown, was appointed a committee to urge on the mayor and city council the establishment of a thoroughly modern board of health.

Influenza Reappearing.—During the past week, new cases of influenza have made their appearance in Baltimore, in several instances death resulting from pneumonia. However, the number is so far not alarming and has not caused the officials at the health department to feel that there will be a fresh outbreak in the city. They are carefully keeping in touch with the situation to be ready to act in any emergency.

MASSACHUSETTS

Medical Student Dies.—William H. Moynihan, Jacksonville, Fla., a student at the University of Maryland, Baltimore, aged 31, formerly medical superintendent of the department of correction, New York City, and later a resident of Jacksonville, Fla., died in that city, October 15, from pneumonia.

Personal.—Dr. Charles E. Donlan, Boston, was reinstated as superintendent of the Long Island Hospital, November 14, by order of Judge Murley of the East Boston Court, who found that Dr. Donlan had been removed illegally by the infirmary trustees, June 21.——Dr. Anna E. Steffen has been appointed resident physician at the Long Island Hospital, to succeed Dr. Llewellyn H. Rockwell, Boston, resigned to enter the military service.——Dr. William B. T. Smith, Bondsville, sustained a fracture of the skull and internal injuries when his automobile plunged over a 20-foot enbankment, near Palmer, November 9. He is under treatment in the Springfield Hospital.

Child Conservation.—The September-October, 1918, number of *The Commonhealth,* the monthly bulletin of the Massachusetts State Department of Health, is a child conservation number. It contains a series of interesting articles on various phases of child care, including the report of the first year's work of the committee on child conservation of the department, by William J. Gallivan, M.D.; the report of the secretary, Richard M. Smith, M.D.; the report of the child welfare supervisors, by Pansy V. Besom, chief; the report of the child welfare department of the woman's committee of the Massachusetts Council of National Defense, by Gertrude W. Peabody, vice chairman, and the following articles: The Part Good Obstetrics Plays in Child Welfare, by Robert L. DeNormandie, M.D.; Infant Feeding, by Richard M. Smith, M.D.; Diet of Older Children, by Fritz B. Talbot, M.D.; The Care and Development of Children, by J. Herbert Young, M.D.; the Importance of School Hygiene in the Scheme of Child Conservation, by Taliaferro Clark, M.D.; Mental Hygiene for Children, by L. F. Emerson, Ph.D.; The Cost of a Well Baby, by Mary Beard, R.N., besides editorial matter and the usual information about communicable diseases, including venereal diseases, vital statistics, etc.

MONTANA

Chiropractor Convicted.—L. J. Certain, Miles City, charged with practicing osteopathy under and by the name of chiropractic, is said to have been found guilty and fined $200. It was brought out in the trial that the defendant had been given instruction and warning, and had been given every opportunity to obtain a license, but had continued to practice without a license.

Hospital News.—An emergency hospital for the reception of influenza patients was opened in the school house in East Helena, November 9. Nursing is under the care of the local Red Cross officials.——Dr. W. Lynn DuBois has purchased a house in Conrad, which has been remodeled and equipped for a private hospital.——Kalispell has secured the Crescent Hotel as a hospital for influenza cases.——Plans have been drafted by the officials of the state university for the erection of a permanent hospital on the campus at Missoula, with accommodation for fifty patients.

Influenza.—November 18, the secretary of the state board of health reported that there were about 8,000 cases of influenza in the state. The situation was such in some districts that the secretary requested the Surgeon-General to allow to remain the physicians of the service sent to the state to aid in combating the epidemic. The Surgeon-General answered that the physicians might remain until December 1 if necessary. Among the places where the situation was bad was Saco, to which place the secretary of the state board went on the date named to take charge, Butte, Missoula, Malta, Geyser, where a physician was needed, and Helena.

NEW JERSEY

Personal.—Lieut. Joseph Watson Martindale, M. C., son of Joseph Martindale, a Camden physician, was wounded during the offensive at Soisson and is convalescing at the Cape May base hospital.

NEW MEXICO

Public Health Administration.—Under department orders of Sept. 16, 1918, Surgeon J. W. Kerr of the Public Health Service began a survey of sanitary organization and administration in the state with the idea of promoting health matters during the war. In his report in *Public Health Reports*, Nov. 15, 1918, a summary is given of the health laws of the state which shows that while the state board of health was organized and given powers of a character to insure an effective administration of health matters within the state, owing to an absence of appropriations to carry out any health regulations the matter has been entirely neglected, the only work of the state board being the attention given to enforcing the medical practice act. All efforts to enforce sanitary regulations throughout the state, therefore, depend on the local authorities. The report states: Little additional legislation is required except that the laws requiring the reporting of births and deaths should be amended somewhat. As a means of defraying the expenses of keeping these records he suggests that fees for marriage licenses be increased and set aside for this purpose. In a long list of recommendations submitted to meet the urgent need of improved health conditions in New Mexico, the chief features are that the present state board of health and medical examiners be designated in law as a state board of medical examiners and that its duties relate to the enforcement of acts to regulate the practice of medicine; that a state department of health be created to exercise all the powers and perform all the duties in respect to health imposed by law on the present board; that the department of health consist of a commissioner of health and a public health council, the commissioner to be paid an adequate salary and devote his whole time to the work.

NEW YORK

Personal.—Dr. William G. Bissell of Buffalo has been chosen president of the New York State Board of Medical Examiners.

OHIO

Personal.—Dr. R. E. Bushong, for eight years assistant superintendent of the State Hospital, Athens, has been appointed acting superintendent of the Dayton State Hospital, to succeed Dr. Erl A. Baber, Dayton, who has been granted an indefinite leave of absence.——Dr. Amon E. Canfield, Toledo, has been appointed local surgeon for the New York Central Lines at Air Line Junction.

Sanitary Unit Plan Urged.—The state board of health has proposed a method of achieving a rapid improvement of sanitary conditions in crowded industrial localities by the organization of sanitary districts, through which the various units now acting independently may adjust their conditions and proceed with a comprehensive program in which the interests of all will be safeguarded. This plan is especially proposed for the lower Mahoning Valley.

Typhoid Fever in the State.—The reported cases of typoid fever in Ohio, in October, were 324 as compared with 344 in October, 1917, and 757 in October, 1916. The September total for this year was nearly 150 cases greater than for September, 1917. The state health officials consider the educational campaign, to reduce the prevalence of typhoid fever in 1918, practically over. There are now being compiled statistics which will give an accurate report on what has been accomplished.

Influenza.—Recurrent outbreaks of influenza throughout the state, chiefly in the rural districts and smaller places, are attributed by the state health officials to premature relaxation of local closing regulations. These outbreaks after conditions had apparently been restored to normal are delaying the final extinction of the epidemic, which caused, up to November 25, an estimated total of 600,000 cases and 12,000 deaths in Ohio. Among places reporting a recrudescence of the disease in greater or less degree are Portsmouth, Newark, Columbus, Cincinnati, Bellaire and New Philadelphia. At Youngstown and Lima the disease was reported to be abating. Out of 1,000 inmates in the state hospital at Lima there were 217 cases and only seven deaths. In this connection the state health department says the epidemic shows up the weakness of health organization in Ohio. There are too many separate health organizations and not enough cooperation and general supervision. Many small communities, town and country, have health boards and health officers, but are too small to support adequate and efficient health departments. Thus, eighty cities, 700 villages and nearly 1,400 townships have their own health officers, but have no adequate supervision by the state. The remedy is to group small districts into larger ones capable of maintaining adequate health service. In the present epidemic this has caused additional work for the state authorities, with consequent delay, and perhaps needless loss of life.

OREGON

Personal.—Dr. James D. Plamondon, staff physician of the Oregon State Hospital for the Insane, Salem, has been appointed superintendent of the Eastern Oregon Hospital for the Insane, Pendleton.

Academy Meeting.—At the meeting of the Portland Academy of Medicine held, November 14, the system which has made possible the examination of 73,238 drafted men with 504 rejections for tuberculosis was described by Major James Matson, M. C., U. S. Army, of the tuberculosis examination board of Camp Lewis, Washington, D. C. The following officers were elected: president, Dr. Edward P. Geary; vice presidents, Drs. George Ainslie and Albert E. MacKay; secretary, Dr. J. Earle Else, and treasurer, Dr. J. C. Elliott King.

PENNSYLVANIA

Personal. — Dr. Charles M. Rickert, Millersburg, has resigned as assistant chief medical inspector.

State Hospital at Selinsgrove.—A new $1,000,000 state hospital will be erected in Selinsgrove in the spring. The state commission has decided on the immediate purchase of lands held under option for this purpose. Dr. Charles S. Aitkens is chairman of the commission.

Influenza Increasing.—The state department of health, November 21, announced that numerous flare-up cases of influenza have been reported in the last two days and an increased number of deaths have occurred in Erie, Johnstown, New Castle, Uniontown, Wilkes-Barre and Allentown. Steps have been taken to reimpose closing orders. The total number of deaths from influenza and pneumonia since October 1 throughout the state is 42,635.

Personal.—Lieut. Frederick B. Shaffer, Somerset, has been reported wounded in the head.——Lieut. Charles C. Ryan, Republic, Fayette County, has been reported as slightly wounded.——Lieut. William Edwin Park, New Milford, Susquehanna County, has been reported wounded, degree undetermined.——Dr. Charles M. Rickert, Millersburg, has been appointed assistant chief medical inspector of the state department of health, to succeed Dr. John J. Mullowney.——Dr. Silas D. Molyneux, Sayre, began his duties as surgeon-in-chief of the Cottage State Hospital, Blossburg, succeeding Dr. William A. DeWitt, Blossburg, deceased.——Capt. Thomas R. Cagion, M. C., Wilkes-Barre, who was wounded in the knee during the Marne fighting, is returning home and will not be able to resume duty in the war zone for some time.——Dr. Mariam E. K. Frisbie, South Williamsport, has been appointed medical supervisor of the state hospital at Somerset to succeed Dr. John S. Marian, who resigned to enter military service.

Philadelphia

Jefferson Students Drop Barracks.—Acting under permission from the authorities of the War Department, Jefferson Medical College will abandon the barracks program and permit the students to lodge at their fraternity houses and dwellings.

Work of the Pennsylvania Hospital Unit.—The Pennsylvania Base Hospital, Unit No. 10, organized in this city as soon as the United States entered the war and sailed overseas, May 18, 1917, with a personnel of 265 physicians, nurses, attendants and orderlies, has been stationed at Traporte, and has treated 78,000 wounded men with a mortality of only 300.

Personal.—Lieut.-Col. James Reid Martin, M. R. C., with the One Hundred and Ninth Infantry Medical Corps, and a former chief resident physician of Jefferson Hospital, was severely burned about the eyes by mustard gas, September 9, during the defense at Chateau Thierry.——Dr. Cornelius T. McCarthy, first lieutenant, Medical Corps, attached to the British army, is recovering from epidemic influenza, in London, England. He was the first American physician to be honored with the British military cross and has been cited twice by the British government. The second time he received a bar to be attached to the cross. He contracted influenza while taking charge of the base hospital in France.——Dr. Bernard Kohn has qualified before the Civil Service Board for director of Public School Medical Inspectors of the Board of Health.——Lieut.-Col. Richard H. Harte, M. R. C., director of the Pennsylvania Base Hospital, Unit No. 10, one of the first American surgical organizations to arrive in France, has just returned home.——Lieut. Andrew Knox, M. R. C., U. S. Army, has been awarded the military cross for attending wounded under heavy machine gun and artillery fire, during the taking of the city of Lille. Lieutenant Knox was attached to the One Hundred and Fifteenth London Regiment, civil service rifle British Expeditionary Forces, although he was a member of the American Army.

SOUTH CAROLINA

Work on Hospital Building Begun.—Work on the addition to the Greenville City Hospital has been commenced. The building when completed will have cost about $125,000.

SOUTH DAKOTA

District Association.—The Third (Madison) District Medical Society of South Dakota, which was organized, July 31, at Ramona, held its annual meeting at Madison, October 16, and elected Dr. Henry H. Frudenfeld, Madison, president, Dr. Blake S. Allison, Madison, vice president, and Dr. John C. Baker, Ramona, secretary-treasurer.

WASHINGTON

To Fight Influena in Alaska.—The steamer *Spokane* left Seattle, November 19, bearing ten physicians, also nurses and medical supplies for the Alaskans suffering from Spanish influenza. Surg. Emil Krulish, U. S. P. H. S., is in command of the party.

Physicians for Alaska.—November 12, a call was issued to the officers of county medical societies throughout the state for volunteer physicians to go to Alaska to help in caring for influenza patients. The call came from the state commissioner of health and the United States Public Health Service.

Personal.—Dr. Charles S. Bumgarner, Davenport, has been appointed health officer of Lincoln County, to succeed Dr. Orville L. Adams, who has resigned to enter the military service. Dr. Adams is at present ill with influenza at the Deaconess Hospital, Spokane.——Dr. Wilson A. Olds, Jr., Addy, is reported to be critically ill with pneumonia.——Drs. Edward P. M. Condon and J. P. Driscoll, Pasco, who have been ill with pneumonia, are reported to be convalescent.——Dr. James H. Ragsdale, health officer of Wapato, has resigned.

Hospital Allowed to Increase Charges.—As the result of an investigation of facilities for handling industrial accident cases in Seattle and Tacoma, the state medical aid board has ordered a radical readjustment of hospital fees under the first aid law. Instead of the $14 a week formerly allowed hospitals for the state industrial accident cases, the medical aid board is now allowing a charge of $18 a week, and has furthermore authorized the chairman of the board to allow this additional fee in hospital in any other locality operating under similar conditions.

WEST VIRGINIA

Arrests for Narcotic Act Violations.—Dr. Thomas L. Nutter and Chesley R. Peck, Clarksburg, and W. A. Dosman, a druggist, are reported to have been arrested at Clarksburg charged with selling narcotics to addicts. After a preliminary examination they were held under individual bonds of $5,000, before the federal grand jury at the coming term at Philippi.——A physician and druggist of Grafton have also been arrested charged with violation of the narcotic act.

Personal.—Dr. S. Marion Steele has been appointed health officer of Moundsville, to succeed Dr. John H. Luikart, who has resigned to enter the military service.——Dr. John W. Ruckman, Rosbys Rock, is reported to be seriously ill with spinal meningitis following influenza.——Drs. William J. Judy and Claude M. Keever, Belleville, are reported to be seriously ill.——Dr. Herbert E. Sloan, Clarksburg, has been appointed a member of the West Virginia State Health Council, to succeed Dr. Floyd F. Farnsworth, Frenchton, resigned to accept the position of director of the division of venereal diseases in the state department of health.

CANADA

The National Sanitarium Association.—At the beginning of the war the daily average number of patients in the institutions of the National Sanitarium Association of Canada was 485. Today it is 688. The expenditure for maintenance has advanced from $275,000 annually to $510,000; and the cost for the present hospital year will probably amount to $585,000. The per capita cost in the free hospitals in Muskoka and Weston has jumped from $10.50 per week to $14.52 per week.

Personal.—Dr. Malcolm M. Crawford has returned from overseas to Toronto, where he will reengage in private practice.——Col. John T. Clarke of the permanent medical service in Canada has gone to Siberia.——Prof. D. Fraser Harris has completed the history of the medical aspect of the great disaster in Halifax, N. S., Dec. 6, 1917.——Dr. John R. Shannon has been elected surgeon-in-chief of the Manhattan Eye and Ear Hospital, New York. He was formerly of Kingston, Ont.——Dr. C. Denton Holmes, Victoria, B. C., medical officer of the Saanich School Board, British Columbia, has tendered his resignation owing to pressure of work in connection with the Invalided Soldiers' Commission.——Lieut.-Col. Donald McGillivray, Toronto, has resumed private practice. He was latterly on the board of consultants. Lieut.-Col. Harold C. Parsons, Toronto, has succeeded him.——Dr. J. Mair Robertson has ceased to be a member of the Medical Board Center, Vancouver, B. C.——Major Horace W. Coates, C. A. M. C., has severed his connection with the Vancouver Military Hospital and has been appointed sanitary officer for the Vancouver military area.——Lieut.-Col. Cameron A. Warren, Toronto, is in command of the Sixteenth Canadian Field Ambulance with the Canadian Siberian Force.——Capt. Harry Whytock, C. A. M. C., was invested with the Military Cross at Buckingham Palace recently by His Majesty, King George.——The Military Cross has been awarded to Capt. John Gagen Lee, Toronto, now with the Imperial Army, but formerly with the C. A. M. C.

GENERAL

Medical Society Meeting Postponed.—Major James L. Andrews, M. C., U. S. Army, formerly chief of the department of health of Memphis, Tenn., announces that the annual meeting of the Tri-State Medical Society of Arkansas, Mississippi and Tennessee will not be held this year, owing to the war conditions and the outbreak of influenza.

Bequests and Donations.—The following bequests and donations have recently been announced:

The New York Hospital, $25,000 as a memorial to his father, by the will of Gerard Beekman.

Post-Graduate Medical School and Hospital, New York City, $25,000 by the will of Frederick Mead.

The Public Health Association and Influenza.—The American Public Health Association has made exhaustive studies of influenza, fearing the recurrence of the epidemic, and bearing in mind that during the original influenza epidemic from 1890 to 1893, the disease was more severe in the second year than in the first. At the coming annual meeting of the American Public Health Association, to be held in Chicago, December 9 to 12, with headquarters in Hotel Morrison, every effort will be made to bring out all the available information regarding the management of epidemic influenza. Among the papers to be presented at this meeting are the following:

Etiology of Influenza, Major William H. Welch, Baltimore; Dr. William H. Park, New York City; Lieutenant-Commander Keegan, and others.

Mobilization of Medical and Nursing Forces, Asst. Surg.-Gen. Joseph W. Schereschewsky, Pittsburgh; Dr. William C. Woodward, Boston, and others.

Influenza and Pneumonia Vaccines, Dr. Edward C. Rosenow, Rochester; Dr. George W. McCoy, Washington, D. C.; Dr. Timothy Leary, Boston, and others.

The Use of Serums in Influenza, Drs. McGuire and Redden; Dr Herman E. Hasseltine, Washington, D. C., and Dr. Joseph Goldberger, Washington, D. C.

The Face Mask, Col. Charles Lynch, M. C., U. S. Army, and Dr. George H. Weaver, Chicago.

The Value of Open-Air Treatment, Surg.-Gen. William A. Brooks, Boston, Massachusetts State Guard.

Organization of State and Federal Forces in Epidemics, Asst. Surg.-Gen. Albert W. McLaughlin, Chicago, and Dr. Eugene R. Kelley, Boston.

History and Statistics of the Epidemic, Asst. Surg.-Gen. Benjamin S. Warren, Washington, D. C.; Dr. William H. Guilfoy, Dr. W. H. Davis, Dr. Lee K. Frankel, New York City, and others.

Reference committees will be appointed who will report on the various phases of epidemic influenza both at the annual meeting and during the year 1919. While extensively devoted to influenza, the program also contains papers on other aspects of public health; mental hygiene, industrial hygiene, social problems, sanitary engineering, etc.

Child Labor Day.—Child Labor Day will be observed throughout the United States, January 25, in synagogues; January 26, in the churches, and January 27, in the schools, according to a bulletin of the National Child Labor Committee. The Children's Bureau of the Department of Labor is arranging to have reports from its field workers available for programs in churches, schools, clubs and other organizations. In this connection the Children's Bureau has issued a bulletin announcing a Back-to-School Drive, the object of which is to return to the schools and keep there the children who have deserted the schools for industry during the war. The actual work of the drive, it is said, will be done through the Child Conservation Section of the Council of National Defense. Committees are now being formed whose duty will be first to study child labor and school attendance laws, and then get accurate lists of the children who have not returned to school. When the child has been compelled for pecuniary reasons to work, an attempt will be made to provide scholarships averaging about $120 a year, and by other methods funds will be provided to enable the children to continue their school courses. It has been the policy of the federal government to refuse to allow the employment of children under 14 in war work, or children between 14 and 16 on war work for more than eight hours a day and six days a week, or between 7 p. m. and 6 a. m. It is believed they should not be allowed to work in the less essential industries. Inquiries made by the Children's Bureau show that in many of the large cities of the country the percentage of children asking for permits to work has largely increased. In Washington this increase has amounted to 295 per cent., and in Wilmington, 61 per cent.

Third Resuscitation Commission Makes Report.—The third Resuscitation Commission, under the auspices of the Committee on Safety Rules and Accident Prevention of the National Electric Light Association met in New York, May 17, 1918, and has just issued its report. There were present P. A. Surg. E. F. Dubois, U. S. N. R. F.; Mr. W. C. L. Eglin, chairman of the committee of the N. E. L. A.; Drs. D. L. Edsall, Yandell Henderson, Joseph Schereschewsky, U. S. P. H. S., William H. Howell, Reid Hunt, secretary of the commission, and S. J. Meltzer, chairman of the commission; Prof. A. E. Kennelly, professor of electric engineering at Harvard and the Massachusetts Institute of Technology; Prof. G. N. Stewart; Lieut.-Col. E. B. Vedder, U. S. Army; Major F. G. Young, Ordnance Department, U. S. Army; Dr. C. A. Lauffer, medical director of the Westinghouse Company; Prof. E. Thomson of the General Electric Company, and conferees from various other interested organizations. Demonstrations of various methods of resuscitation were given and special devices exhibited.

STATEMENT OF IMPORTANT FACTS

In the discussion following the presentation of methods and evidence to the commission the following important facts were emphasized:

1. That in most accident cases no resuscitation apparatus is at hand for immediate use.
2. That reliance on the use of special apparatus diminishes greatly the tendency to train persons in the manual methods and discourages the prompt and persevering use of such methods.
3. That police officers or physicians often interfere with the proper execution of manual methods, in that they direct that the patient be removed in an ambulance to some hospital, thus interrupting the continuance of artificial respiration.
4. That in many hospitals the members of the staff are not all acquainted with the methods of artificial respiration.
5. That in medical schools instruction is not properly provided for students in the manual methods of artificial respiration.

RESOLUTIONS ADOPTED BY THE COMMISSION

In view of these facts the following resolutions were adopted by the commission.

1. The prone-pressure or Schäfer method of resuscitation is preferable to any of the other manual methods.
2. Medical schools, hospitals, fire and police departments, the Army and Navy, first aid associations, and industrial establishments in general, should be urged to give instruction in the use of the prone-pressure method of resuscitation.
3. Individuals who, from accident or any other cause, are in need of artificial respiration, should be given manual treatment by the prone-pressure method immediately on the spot where they are found. It is all important that this aid be rendered at once. The delay incident to removal to a hospital or elsewhere may be fatal, and is justifiable only where there is no one at hand competent to give artificial respiration. If complications exist or arise, which require hospital treatment, artificial respiration should be maintained in transit, and after arrival at the hospital, *until spontaneous respirations begin*.
4. Persons receiving artificial respiration should, as much as possible, be kept warm and the artificial respiration should be maintained till spontaneous breathing has been permanently restored, or as long as signs of life are present. Even in cases where there is no sign of returning animation, artificial respiration should be kept up for an hour or more.
5. A brief return of spontaneous respiration is not a certain indication for terminating the treatment. Not infrequently the patient after a temporary recovery of respiration stops breathing again. The patient must be watched and if normal breathing stops, the artificial respiration should be resumed at once.
6. Artificial respiration is required only when *natural respiration has ceased*. In cases of simple unconsciousness from any cause in which natural respiration continues, artificial respiration should not be employed without medical advice.
7. The commission recommends that in cases of gas asphyxiation, artificial respiration, whether given by a manual method or by special apparatus, should be combined when possible with the inhalation of oxygen from properly constructed apparatus.
8. With regard to the employment of mechanical devices for artificial respiration the commission feels that it ought not at present take a definite stand, either for or against any particular form of apparatus. However, the commission recommends, that the use and installation of apparatus should be confined, for the present, to properly equipped institutions under medical direction. The commission recognizes the great need of simple devices capable of performing artificial respiration reliably and efficiently. It therefore recommends a careful study of the problem, directed toward *the development of a reliable method appropriate for general adoption.* Such studies can best be carried on in properly equipped hospitals and laboratories which offer opportunities and facilities for critical observation and experimentation.

The commission consists of fifteen members. Fourteen approved the foregoing report without qualifications. The fifteenth member, Dr. Yandell Henderson, wishes to qualify his vote by a special statement:

STATEMENT OF DR. YANDELL HENDERSON

"While I concur in a considerable part of the report of the Resuscitation Commission I dissent from the statement in Resolution 8 recognizing 'the great need of simple devices capable of performing artificial respiration reliably and efficiently.'

"Devices which are excellent from the mechanical standpoint are now available and widely sold; but the evidence regarding them indicates clearly, I believe, that even if these devices were on the spot where several gassings or electrocutions occurred, and if all the victims were treated with them, except one who was given manual (prone pressure) treatment, this one would have much the best chance of recovery. In actual practice the apparatus is seldom right on the spot adjusted and ready. Critical time is lost, and thus in the above supposititious cases, as they actually occur, the only victim with any considerable chance of resuscitation (aside from those who recover spontaneously and are credited to the apparatus) is the one treated manually.

"Even more important is the fact, demonstrated now by universal experience, that when apparatus is known to be obtainable, it is sent for and the manual method neglected. Thus today the apparatus in public use is on the whole contributing very materially to decrease the saving of life."

The committee voted to continue its existence, electing as president, Dr. L. J. Meltzer; vice president, Dr. Yandell Henderson; secretary, Dr. Reid Hunt; treasurer, Mr. W. C. Eglin.

FOREIGN

Ether Day in London.—Ten years ago the trustees of the Massachusetts General Hospital set apart October 16 as "Ether Day" in commemoration of the first public demonstration and practical introduction of anesthesia in surgery. This year the day was celebrated in London by about twenty of the old house physicians and surgeons of the Massachusetts General Hospital who are attached to the various American base hospitals in England. Colonel Washburn, now in charge of American hospitals in England, presided as chairman, and General Winters and Sir William Osler were the guests of honor. Dr. Osler told the story of the introduction of surgical anesthesia. The original papers of Bigelow and Warren and those of William T. G. Morton were exhibited.

Pekelharing Souvenir Volume.—The fiftieth professional anniversary of Prof. C. A. Pekelharing, of the chair of physiologic chemistry and histology at the University of Utrecht, has been celebrated by the issuance of a *livre jubilaire* as the bulky fourth number of the second volume of the *Archives Néerlandaises de Physiologie de l'homme et des animaux*. There are nearly forty articles in the number, most of them reporting results of original research, including Einthoven's "Sur les phénomènes électriques du tonus musculaire," Magnus' article on the muscular reflexes in decerebrated monkeys (in German); De Waard's "Ultrafiltration de petites quantités de liquide par la force centrifuge"; Halliburton's "The Rôle of Fats in Diet"; Beijerinck's report on a new biologic reaction with iron, "Chromogenic Yeasts," and De Haan's "Influence of Calcium Salts on Phagocytosis" (in French).

Fees for Medical Advice by Telephone.—A Netherlands medical journal announces that the physicians of Utrecht have decided to charge half the rates for an ordinary medical call for advice by telephone. The journal insists that this remuneration is not sufficient. The applicant—usually well to do, with his private telephone—is spared the trouble of a call at the doctor's office and waiting in the anteroom, and yet he gets the advice desired. It surely should be left to the physician, it remarks, whether he shall charge according to the service rendered, the half or the full amount of the ordinary office fee. The *Nederlandsch Tijdschrift* comments that however the matter is decided, the discussion will have an educational effect on the public, allowing it to be understood that a telephone call, compelling the physician to get up from his meal, his book, his repose, or his work is not a gratuitous extra but something that has to be paid for. The Prussian tariff recently promulgated provides for fees from about 40 cents to $1.25 for telephone advice.

Professor Henkel Acquitted.—The cable dispatches last August related that Prof. Max Henkel, of the chair of gynecology and obstetrics at the University of Jena, was being tried for the death of a woman on whom he had operated although warned by the nurses that the woman had not been prepared for an operation. He is said to have hastened the operation because a visitor was present, Prince Bernhard of Lippe, a layman, who likes to watch gynecologic operations. The *Nederlandsch Tijdschrift* now announces that the sentence acquitting Professor Henkel stated further "The admittance of lay persons interested in science to witness operations is to a certain degree customary and is not a matter for scandal." The medical faculty at Munich had published a statement taking the opposite view.

Municipal Milk Supply.—According to *Commerce Reports*, owing to the difficulty of securing a sufficient quantity of pure milk at a reasonable price at Wellington, New Zealand, steps have been taken by the city council to handle milk as a municipal undertaking. The council has obtained authority to make the milk business a monopoly in the city. The move is being observed with interest by the dairymen and by other municipalities.

PARIS LETTER

Paris, Oct. 31, 1918.

The Fight Against Influenza

In view of a decided recrudescence of grip of grave degree with bronchopulmonary complications, the minister of the interior has asked the Académie de médecine to appoint a commission which will devise ways and means to combat the existing epidemic of this disease. This commission consists of Professors Netter, Bezançon, Achard, Vincent and Chauffard.

M. Albert Favre, undersecretary of state of the ministry of the interior has sent instructions to all prefects as to the best means for combating the grip. These instructions require that physicians must report cases of grip—a new regulation. If the epidemic continues to progress, all meetings or gatherings of large numbers of people, as in theaters, market places, movies, etc., must be interdicted. But, such measures are not to be taken until consultation is had with the Conseil départemental d'hygiène.

Influenza in Switzerland

Word has been received that the epidemic of so-called "Spanish" grip has broken out with renewed severity at Geneva. Therefore, the Commission d'hygiène has asked the Conseil d'Etat de Genève to close all theaters and movies, and to stop all public gatherings. A certain number of schools have already been closed and several other measures of a general nature have been ordered.

Sanatoriums in the Mountains

In various regions of France great activity has been displayed in the establishment of sanatoria in the mountains for the treatment of tuberculous soldiers. An interesting meeting was held recently in Dauphiné of representatives of several of these zones, on the suggestion of Dr. Perret. The medical profession, the universities and industry were represented at this meeting. The consensus of opinion was that in France locations for sanatoriums may be found that are far more desirable than the mountains of Switzerland (which are too humid), especially the region of the Hautes Alpes in southeastern France. High altitudes are available; the climate is exceptional, dry and sunshiny, like the Mediterranean climate. The commission selected several locations at 1,800 meters altitude.

Announcement is also made of the establishment of a sanatorium at a lower altitude on the plateau of Petites Roches, near Saint Hilaire on the outskirts of Grenoble. This establishment, located at an altitude of 1,100 meters, will be given over for the use of the Association métallurgique et minière contre la tuberculose, an association created under the auspices of the Comité des Forges de France. Mme. la baronne M. de Rothschild has founded at Mégève (département de la Haute-Savoie) a *station de cure* with several hotels, treatment and rest rooms and a *collège sportif* (gymnasium).

French Orthopedic Society

The Société française d'orthopédie has been organized. The president is Dr. Kirmissòn, professor of clinical surgery and diseases of children on the Paris medical faculty, and the vice presidents are Dr. Auguste Broca, professor of operative surgery in the Paris medical faculty and Dr. Dénucé, associate professor in the Bordeaux medical faculty. The secretary-general is Dr. Nové-Josserand, associate professor in the Lyon medical faculty; the treasurer is Dr. Estor, clinical professor of surgery of children and of orthopedics in the Montpellier medical faculty. The first annual meeting of the society will be held in October, 1919, in the buildings of the Paris medical faculty at the same time as the Congrès de chirurgie. The following subjects will be discussed: (1) amputations in relation to subsequent prostheses; (2) spondylitis during the war; (3) treatment of pseudarthroses.

American Red Cross Activities

The American Red Cross has opened a new *Exposition de l'enfance* at Toulouse. At the opening exercises, the mayor of Toulouse, in the name of the city, extended thanks to the United States, and particularly to the American Red Cross which is continuing its beneficent work in France.

Extraction of Intrathoracic Projectiles

So far as intrapleural projectiles are concerned, there is general agreement that they should, as a rule, be extracted, and this rule is practically without exceptions. The discussion held at the recent Congrès français de chirurgie made it clear that this rule does not apply to intrapulmonary projectiles.

Dr. R. Grégoire of Paris extracts all intrapulmonary projectiles because of the complications which they may entail, sooner or later, anatomicopathologic examinations having shown that these foreign bodies are rarely aseptic. On the other hand, Dr. Duvergey of Bordeaux says that some exceptions must be made, depending on the gravity of the general condition of the patient. Dr. Viannay of Saint Etienne is in favor of immediate intervention; he operates as soon as the patient can be made ready, except when the projectile is small, because such do not give rise to any functional disturbance.

Dr. Petit de la Villéon of Bordeaux advises to refrain from operating at advanced stations. He says that surgery of the lung is surgery for base hospitals. Operative procedures at the front should be confined to the toilet of the chest wall, excision of dead tissues and structures, removal of pieces of clothing, excision of the tract of the projectile, reserving the invasion of the lung for a later period, the operation *à froid* being very benign as compared to operation *à chaud*. The conditions are practically the same as in the case of appendicitis—operating not at the height of the attack but during the interval. Whenever the general condition of the patient is not grave, he should be evacuated to the rear. When he arrives at the rear, is it necessary to extract all intrapulmonary foreign bodies? Petit de la Villéon says that the gravity and danger of the operation itself must be considered; all projectiles which can be removed with forceps with the aid of fluoroscopy should be removed. Whenever thoracopneumonotomy is required, it is necessary to decide whether, under the circumstances, it is better to operate or to refrain from doing so. Dr. Rocher stated that it is always difficult to decide on intervention when the intrapulmonary foreign body is small and occasions only slight symptoms, such as dyspnea on effort, or chest pains. If these pains are due to a chronic pleuritis or an intercostal neuralgia, then the extraction of the foreign body will, in all probability, leave the situation unchanged.

Bombardment of Hospitals by the Germans

In a letter addressed to M. Margaine, deputy from the département de la Marne, M. Clemenceau confirms the report that on October 1 a German aeroplane bombarded the hospitals of Châlons. This was not the first time that the enemy had broken the conventions which until then had been observed by all civilized nations, carrying death and destruction into the midst of hospital formations.

In connection with these facts it is interesting to note what was said recently by Mr. Orlando, the Italian premier, in the Italian chamber of deputies, to the effect that during the victorious naval operations at Durrazzo, the Austrian hospital ship had been respected and carefully protected.

Women Physicians Affiliated with the Medical Department of the French Army

Hereafter all French women who possess a medical diploma are eligible to appointment as "doctoresses adjointes au Service de Santé militaire," and will receive the pay, perquisites and allowances of an *aide-major* of the second class—a sublieutenant. Women medical students who have received twelve inscriptions may be appointed "assistantes du Service de Santé militaire," and receive the pay and allowances of a *médecin auxiliaire.* The minimum length of service will be six months, and these appointees will serve under the *médecins-chefs* of their formation, the directors of the Service de Santé militaire, and the superiors of the Service de Santé des armées.

International Scientific Representation

On the initiative of the Royal Society of London, delegates from the scientific academies of the allied countries will soon meet in London for the purpose of outlining the course to be pursued in the future with reference to the cooperation of subjects of the Central Powers in international scientific activities after the war. France will be represented at this conference by MM. Picard and Lacroix, permanent secretaries of the Académie des Sciences, and by MM: Bigourdan, Bailland, Haller, Lallemand and Moureu, members of the same academy.

Establishing a Chair of American Literature at the Sorbonne

In France American literature has been taught by the chair of English literature, never as a separate entity. Now, however, by decree of the minister of public instruction, a separate chair of American literature will be established at the Sorbonne under the professorship of M. Cestre, professor in the University of Bordeaux, and a former student of Harvard University, where he served during the session of 1917-1918 as exchange professor.

French Congress of Surgery

The twenty-seventh Congrès de l'Association française de chirurgie was opened, October 7, under the presidency of Dr. G. Maunoury, surgeon on the staff of the Hôtel Dieu de Chartres. The opening session was presided over by Dr. Louis Mourier, under-secretary of state of the Service de Santé militaire. In his opening address Dr. Mourier thanked the medical corps for its devoted services during the war.

LONDON LETTER

London, Oct. 31, 1918.

A New Medical Department for Dealing with Disabled Soldiers

The number of disabled soldiers discharged from the army under treatment directed by the ministry of pensions now amounts to 30,000. It has been decided to establish a new medical department for the purpose, and Sir John Collie has been appointed medical director. The first step taken by the newly formed department was to complete arrangements with all existing general hospitals that could spare accommodation to provide treatment of the character required. It soon became obvious that this accommodation was insufficient. There are also certain disorders from which the discharged men suffer for which little, if any, accommodation existed. To deal with them it has been necessary to provide and arrange for special institutions. Six homes of recovery for men suffering from neurasthenia and shell shock have already been opened, and three more are being rapidly prepared. These institutions are under the care of specialists on nervous disorders, and every opportunity is given for effecting complete cure. It has been decided that special arrangements must be made for the large number of paralyzed men. For obvious reasons it is undesirable that cases of this sort should be dealt with in general hospitals. Steps, therefore, are being taken to establish in each country, in connection with hospitals, separate institutions where these men will be readily accessible to their friends. It would be an addition to their already grievous plight if they were segregated in one large institution and cut off from personal contact with their friends and relations. These cases require exceptional treatment, and it is hoped, in addition to what the medical department can do in the way of service and allowances, to enlist the sympathies of special committees of influential people who will take a personal interest in providing amusements, entertainments, and the various little luxuries and attention that mean so much to men in this condition. The capitation grants sanctioned by the treasury will cover only the actual cost of the treatment and nursing, which in these cases is very expensive. Special arrangements have been made at most of the spas for the treatment of rheumatic patients, and hostels have been provided and are in the course of provision to accommodate the men. The large number of orthopedic cases (which embrace practically all injuries to limbs) has also necessitated special arrangements. Orthopedic surgery has greatly developed during the war. A scheme is on foot for setting up annexes in connection with the special military surgical hospitals. The treatment of the discharged man in these annexes will be kept entirely distinct from that of the serving soldier, but the supervision of the treatment and the decisions as to operations will be undertaken by the specially skilled staff at the disposal of the War Office. In addition, outpatient clinics for orthopedic treatment of discharged men will be established as occasion requires. It is expected that in each large town of 50,000 inhabitants or more a clinic will be established which will be supervised by surgeons from the special military surgical hospitals. Special aural boards have been established in London and the provinces to regulate the award of pensions and determine the treatment and training to be given men discharged on account of deafness and the various forms of ear disease. Special aural clinics have also been established for giving treatment of this character when it cannot be obtained at hospitals, and classes have been formed to give instruction in lip reading to those who are totally deaf.

Physicians' Action Against the British Medical Association

An important libel action has been decided against the British Medical Association. It was brought by four physicians who claimed damages for conspiracy to injure them in their profession and to libel and slander them. They had been medical officers of the Coventry Provident Dispensary, an approved institution under the national health insurance act of 1911. The members paid a small subscription and in return received from the dispensary medical attendance during illness. The dispensary was begun in 1831, and in 1888 it had 20,000 members. In 1906 the British Medical Association became very hostile to the dispensary on the grounds that canvassing of the public for patients by a collector paid by commission was improper, that the management was too exclusively in lay hands, and that there was no proper wage limit for the subscribers. As a result, five of the medical staff resigned, a new medical club was started under the auspices of the British Medical Association, and an attempt was made to prevent the dispensary obtaining medical service. However, four physicians continued in the employment of the dispensary. The Coventry division of the British Medical Association, supported by the central organization, then endeavored to make things unpleasant for them. Members of the Association were forbidden to enter into professional relations with the medical officers of the dispensary. Thus if the opinion of a consultant was required in a case, the patient had first to discharge the dispensary physician and place himself under an outside one before he could obtain this.

Mr. Justice McCardie delivered a long judgment occupying four hours. He said that it was clear that the aim of the defendants was to inflict professional ruin on any physician who broke the rules of the local body or any rule that might be made by the head body itself. That grave power was used not only against the members of the defendant association but also against those who had never belonged to it. The defendants claimed to enforce by boycott their own standard of medical honor and interest throughout the country. That point was momentous; it touched the vital interests of every physician. He might be exposed to degradation and dishonor at the will of a body that was void of the slightest statutory authority. Such authority was conferred on the General Medical Council, a body of physicians appointed for disciplinary purposes. But the British Medical Association had taken to itself a jurisdiction more far-reaching, and perhaps, more potent than that of the General Medical Council. It entrusted to a large extent the standard of "the honor and interest" of the medical profession to a number of scattered bodies throughout the country, which varied in numbers, inclination, views and self-interest. A branch or division might make a rule to suit its own local pecuniary interest. If such a rule should be broken by a physician, were he a member of the Association or not, he became subject to a declaration that he had acted against the honor and interests of the medical profession. On that declaration there followed a local condemnation, and on that local condemnation there might result a merciless boycott and ruin. What had the plaintiffs done? They had merely accepted posts as the medical officers of a highly respectable and ably managed dispensary on terms that gave them ample remuneration of some $3,000 or $3,500 a year, a full opportunity of private practice, and adequate leisure. Their only fault lay in the fact that this acceptance prevented the local physicians from achieving their wish of either capturing or destroying the Coventry dispensary. The alleged sin was a financial rather than a moral one. The pecuniary interests of the Coventry physicians lay at the root of the matter. The question of ethics—medical or otherwise—had nothing to do with the case; and the assertion that the plaintiffs had been guilty of conduct against the "honor" of the profession could not, in his view, be supported. The honor of the medical profession was amply protected by the wide powers entrusted to the General Medical Council by Parliament. He could not view with favor the assumption by the British Medical Association of a coordinate jurisdiction and the enforcing of the varying views of medical honor with weapons of ostracism, intimidation and threat. The plaintiffs were boycotted and punished and pecuniarily damaged without just cause in law. The plaintiffs did not sin against the "honor" of the medical profession within any fair meaning of that word.

The judge next considered the question of motive and malice in relation to a cause of action based on the pecuniary injury inflicted by the employment of unlawful means. Actual malice was not necessary in such an action for molestation as the present, and it was only necessary to prove the use of illegal means, such as violence or threats. The motives, feelings and objects of the defendants were mixed. Their conduct was doubtless instigated to a large extent by the desire to protect the local pecuniary interests of the Coventry physicians, and the general interests of the profession. But, on the other hand, the defendants were angrily hostile to the plaintiffs. They sought every opportunity of inflicting humiliation, and they evidently wished to render the lives of the plaintiffs unbearable. They desired to do far more than merely to protect their interests. They desired to punish the plaintiffs as a separate end in itself, and they meant to make that punishment bitter to the last degree. The judge gave damages against the association in varying sums for the four plaintiffs aggregating $14,000.

Marriages

CAPT. LAWRENCE LEWELLYN CRAVEN, M. C., U. S. Army, East Penn, Iowa, on duty at Kelly Field, San Antonio, Texas, to Miss Lena L. Newton of Kalamazoo, Mich., at San Antonio, November 14.

MAJOR ELMER ELLSWORTH HEG, M. C., U. S. Army, Seattle, on duty at Camp Jackson, S. C., to Miss Evelyn R. Sampson of White River Valley, Wash., at Seattle, October 14.

RAYFORD KENNEDY ADAMS, Raleigh, N. C., to Miss Mary Belle King, at Charlotte, N. C., November 2.

HARRY IRVING PARTRIDGE to Mrs. Josephine Houkins Jennings, both of Syracuse, N. Y., November 5.

ZACHARIAH BRAINERD, Hunnewell, Mo., to Miss Mona Alexander of Leesburg, Mo., September 13.

GEORGE ELLIOTT EBRIGHT to Miss Florence Braverman, both of San Francisco, November 7.

WILLIAM E. PARKE, to Miss Grace Woods, both of Philadelphia, November 12.

Deaths

Charles W. Brown, Washington, D. C.; Long Island College Hospital, Brooklyn, 1871; aged 72; a member of the Medical Society of the District of Columbia; lecturer on surgery to the Lucy Webb Hayes Training School, and surgeon to the Sibley Memorial Hospital; formerly physician to the Elmira (N. Y.) State Reformatory; health officer of Elmira for two terms; secretary and president of the Tioga County (Pa.) Medical Society; secretary of the Elmira Academy of Medicine; secretary and president of the Third District Branch of the New York State Medical Association; died at his home, November 10, from carcinoma of the stomach and aneurysm of the descending aorta.

Lieut. Ira Condict Whitehead, Jr. ⊕ **M. C., U. S. Army**, Hoosick, N. Y.; Albany (N. Y.) Medical College, 1912; aged 32; who was on duty with the British Expeditionary Forces in Flanders in 1917, and was invalided from there to the Prince of Wales Hospital, London, thence to Osborne House on the Isle of Wight, and then to Netley Hospital, where he was found to be suffering from nerve shock and cholecystitis, and was returned to the United States and placed in the U. S. Army Hospital No. 1, Williamsridge, and honorably discharged on account of physical disability, Aug. 16, 1918; died at his home, October 27, from pneumonia.

Lieut. William Frederic Craig ⊕ **M. C., U. S. Army**, Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; aged 44; a specialist in neurology; for fifteen years professor of biology, anatomy and French in the Central High School; who entered the military service in May, 1917, and was on duty at Camp Oglethorpe, Ga., Camp Weir, and finally assigned to duty with the Three Hundred and Fifteenth Infantry at Camp Meade, Md., and went to France with the Seventy-Ninth Division; was killed, September 26, while caring for wounded soldiers northwest of Verdun, France.

Capt. Henry Guild Burton ⊕ **M. C., U. S. Army** (retired), San Francisco; New York University, New York City, 1869; aged 71; formerly clinical assistant to the chair of ophthalmology in the San Francisco Polyclinic and the Medical Department of the University of California, and assistant surgeon to the Pacific Branch of the National Home for Disabled Volunteer Soldiers, Los Angeles; who entered the Army as assistant surgeon in 1876, and was retired Feb. 5, 1902, on account of disability in line of duty; died, recently, at his home.

Capt. James Frederick Munson ⊕ **M. C., U. S. Army**, Sonyea, N. Y.; University of Michigan, Ann Arbor, 1904; aged 37; for twelve years pathologist at the Craig Colony for Epileptics, Sonyea, and for several years secretary of the National Society for the Study of Epilepsy; formerly assistant in hygiene in his alma mater; died at his station, Plattsburg, N. Y., October 25, from influenza.

George E. Spear, Lincoln, Neb.; University of Nebraska, Omaha, 1903; aged 45; formerly a member of the Nebraska State Medical Association; a member of the Association of Military Surgeons of the United States; a member of the staff of the Ingleside State Hospital from 1905 to 1907; who was shot by a nurse in Lincoln, November 11, died from his wounds, November 12.

Charles Ransom Johnson, Kansas City, Mo.; University Medical College, Kansas City, Mo., 1905; aged 55; assistant to the chair of practice of medicine and assistant demonstrator of anatomy in his alma mater; formerly superintendent of the Kansas City General Hospital and the Leeds Municipal Hospital; died in Grace Hospital, Kansas City, November 10.

Henry E. Jones, Portland, Ore.; Bellevue Hospital Medical College, 1869; aged 80; acting assistant surgeon, U. S. Army; emeritus professor of clinical gynecology in the University of Oregon, Portland; a veteran of the Civil War, in which he served as surgeon in the Confederate Service; died at his home, November 9, from heart disease.

George A. Stewart, Brookport, Ill.; Louisville (Ky.) Medical College, 1889; aged 55; a member of the Illinois State Medical Society; local surgeon to the St. Louis and East St. Louis Suburban Railroad Company; died in Centropolis, Ill., October 31, as the result of rupture of the gallbladder.

Frank Leland Mitchell ⊕ Liberty, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1903; aged 45; while driving in his automobile over the Chesapeake and Ohio tracks, at a grade crossing near Kitchell, Ohio, October 28, was struck by an engine and instantly killed.

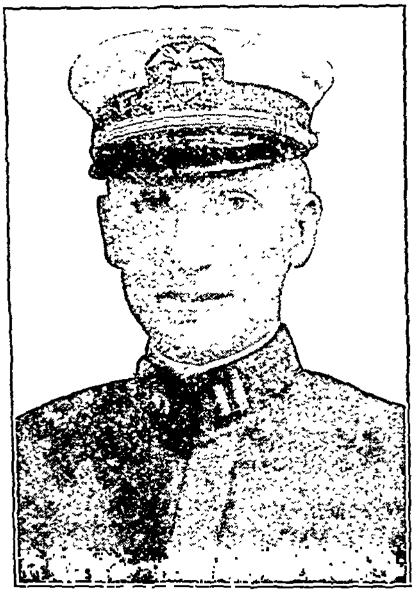
Stanley W. Edwins, Ellwood, Ind.; Cincinnati College of Medicine and Surgery, 1870; aged 82; for several years local surgeon to the Panhandle System; from 1878 to 1882 a member of the state legislature; died at his home, November 16, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent.

Louis N. Wilson, Baltimore; College of Physicians and Surgeons, Baltimore, 1876; aged 66; for thirty-three years a practitioner of Mardela Springs, Md.; formerly a member of the Medical and Chirurgical Faculty of Maryland; died at his home, November 14, from heart disease.

Putnam Dickinson, Des Arc, Ark.; Missouri Medical College, St. Louis, 1880; aged 69; formerly president of the Prairie County Board of Health and vice president of the Prairie County Medical Society; died at his home, November 9, from pneumonia following influenza.

Lieut.-Com. Frank Pennybacker White Hough ⊕ P. A. Surg., U. S. Navy; on duty on *U. S. S. Huron;* University of Virginia, Charlottesville, 1907; aged 34; who entered the Navy, April 11, 1908; died on board the *U. S. S. Huron,* October 27, from bronchial pneumonia.

Charles Pulford Forward, Dubuque, Iowa; Washington University, St. Louis, 1912; aged 29; a member of the Iowa State Medical Society; a specialist in pediatrics; died in Finley Hospital, Dubuque, November 11, from influenza.



Died in the Service
LIEUT. WILLIAM H. BUFFUM, M. C., U. S. NAVY, 1877-1918
(See The Journal, last week, p. 1760)

Thomas Rutherford Savage, New York City; College of Physicians and Surgeons in the City of New York, 1874; aged 66; physician to the French and Presbyterian hospitals, and to the outpatient department to St. Luke's Hospital; died at his home, November 12.

John William Batte, Nashville, Tenn.; Jefferson Medical College, 1846; aged 95; for fifty-four years a practitioner of Pulaski, Tenn.; died in St. Thomas' Hospital, Nashville, from the effects of concussion of the brain sustained in a street car accident, October 21.

Frank E. Lewis Brecht ⊕ Buffalo; University of Buffalo, N. Y., 1872; aged 73; a member of the Buffalo Academy of Medicine; assistant health physician of Buffalo during the smallpox epidemic of 1872; died at his home, October 29, from influenza.

Lieut. Oscar Miller Klingen ⊕ M. C., U. S. Army, Minneapolis; University of Minnesota, Minneapolis, 1916; aged 29; who went to France with Base Hospital No. 26, in June, 1918, died at his post, October 16, from pneumonia following influenza.

Isaac H. Lent, Middletown, N. Y.; Albany, (N. Y.) Medical College, 1873; aged 72; a member of the Medical Society of the state of New York; consulting ophthalmologist to Thrall Hospital, Middletown; died at his home, about October 20.

Lieut. Arthur Morgan Evans ⊕ *M. C.*, U. S. Army, Chicago; University of Illinois, Chicago, 1916; aged 28; died in Evacuation Hospital No. 21, Camp Custer, Battle Creek, Mich., October 5, from cerebrospinal meningitis.

Julius H. Ruhl, Galveston, Texas; University of Texas, Galveston, 1899; aged 40; a member of the State Medical Association of Texas; demonstrator of obstetrics in his alma mater; died at his home, November 10.

Chadwick Evans Arnold, San Jacinto, Calif.; Cooper Medical College, San Francisco, 1901; aged 41; formerly in the United States Indian Service; died at his home, November 7, from pneumonia following influenza.

James Walter G. McLaughlin ⊕ Georgetown University, Washington, D. C., 1908; aged 35; director of the State Bank of Beaver Falls; died at his home, November 10, from pleuropneumonia following influenza.

Clifford F. Morell, Brainerd, Minn.; University of Minnesota, Minneapolis, 1914; aged 31; a member of the Minnesota State Medical Association; died at his home, November 13, from pneumonia following influenza.

Lieut. Francis Marion Burkhalter ⊕ M. C., U. S. Army, Ray City, Ga.; Atlanta (Ga.) School of Medicine, 1909; aged 31; who arrived in France, July 20, died there on October 8, from lobar pneumonia.

David Q. Will, Moore's Store, Va.; Maryland Medical College, Baltimore, 1902; aged 40; a member of the Medical Society of Virginia; died at his home, November 13, from pneumonia following influenza.

Capt. Lawrence Edward Flannagan ⊕ M. C., U. S. Army, Charlottesville, Va.; University of Virginia, Charlottesville, 1884; aged 54; died at his home, about November 6, from pneumonia following influenza.

William Hampton Caldwell, Houston Heights, Texas; Baltimore (Md.) College, 1883; aged 60; a member of the staff of St. Luke's Hospital, Houston; died at his home, November 10, from pneumonia.

Pierre Leonard Couillard, Manchaug, Mass.; Montreal School of Medicine and Surgery, 1875; aged 68; a member of the Massachusetts Medical Society; died at his home, October 11, from pneumonia.

Edward A. Hudson, Edison, Neb.; Missouri Medical College, St. Louis, 1890; aged 51; a member of the Nebraska State Medical Association; died in Cambria, Neb., October 7, from cerebral hemorrhage.

Alfred Marius Wang ⊕ Minneapolis; Northwestern University Medical School, Chicago, 1886; aged 57; attending physician to St. Mary's Hospital, Minneapolis; died at his home, November 13.

Samuel Berlin, Brooklyn; Long Island College Hospital, Brooklyn, 1916; aged 26; a member of the staff of Fordham Hospital; died at Fort Slocum, N. Y., October 16, from bronchial pneumonia.

James Frankland Boyle, Edmonton, Alta.; University of Toronto, Ont., 1896; L.R.C.P., L.R.C.S., Edinburgh, L.R.F.P. and S., Glasgow, 1903; aged 46; died, recently, in Edmonton, from influenza.

Horace Charles Newbury, Chicago; University of Pennsylvania, Philadelphia, 1918; aged 24; an intern at the Ravenswood Hospital; died, November 19, from pneumonia following influenza.

Edward Everett Hamblen, Bedford, Mass.; Tufts College, Boston, 1898; aged 53; a member of the Massachusetts Medical Society; town physician of Bedford; died at his home, November 10.

C. A. Edwards, Doerun, Ga.; Atlanta (Ga.) Medical College, 1898; a member of the Medical Association of Georgia; died at his home, about November 8, from pneumonia following influenza.

William L. Creswell, Danbury, Iowa; State University of Iowa, Iowa City, 1903; aged 40; died in St. Vincent's Hospital, Sioux City, Iowa, October 22, from pneumonia following influenza.

Aaron Dudley French, Allendale, Ill.; Barnes Medical College, St. Louis, 1904; aged 42; a member of the Illinois State Medical Society; died at his home, October 17, from pneumonia.

Daniel W. Jones, Princess Anne, Md.; Jefferson Medical College, 1848; aged 95; for several years chief judge of the orphan's court of Somerset County; died at his home, November 12.

Nathan Kendall Mills ⊕ Odanah, Wis.; St. Louis University, 1911; aged 36; government physician at Odanah; died at that place, November 9, from pneumonia following influenza.

Dolphus L. Stevens ⊕ Foreman, Ark.; College of Physicians and Surgeons, Little Rock, Ark., 1910; aged 35; died at his home, October 24, from pneumonia following influenza.

Frederick William Cuyler Lockwood, Greenwich, Conn.; Eclectic Medical College of the City of New York, 1885; aged 62; also a druggist; died at his home, November 13.

Edward Kennedy Henderson, *Haliburton, Ont.*; University of Toronto, 1909; aged 30; medical officer of the Haliburton County Battalion; died at his home, about November 10.

James Todd Duncan ⊕ Toledo, Ohio; Northwestern University Medical School, Chicago, 1905; aged 41; died at his home, October 24, from pneumonia following influenza.

William F. Holden, Winona, Minn. (license, exemption certificate, Minnesota, 1883); aged 67; a practitioner for forty-six years; also a druggist; died at his home, October 30, from organic heart disease.

John Galbraith Martin, Anton Chico, N. M.; Washington University, St. Louis, 1904; aged 35; a member of the New Mexico Medical Society; died, about November 10.

Sebastian Keller, Spokane, Wash.; University of Wurzburg, Germany, 1854; aged 88; for thirty-six years a practitioner of West Bend, Wis.; died at his home, November 3.

Charles Raymond Atzen, Omaha, Neb.; John A. Creighton Medical College, Omaha, 1915; aged 27; died at his home, November 2, from pneumonia following influenza.

Alva W. Wilder, Fort Smith, Ark.; Atlanta (Ga.) Medical College, 1884; aged 59; at one time a member of the Arkansas Medical Society; died at his home, November 14.

Walter Booker England ⊕ Huntsville, Ala.; University of Tennessee, Nashville, 1904; aged 35; died at his home, October 12, from pneumonia following influenza.

Lucien Clyde Davis, Lakewood, Wis.; Ensworth Medical College, St. Joseph, Mo., 1903; aged 40; died at his home, about November 2, from lobar pneumonia.

Zachariah Brainerd, Hunnewell, Mo.; University of Missouri, Columbia, 1885; aged 57; died at his home, November 2, from pneumonia following influenza.

Charles Anthony Ordway ⊕ Everett, Mass.; Dartmouth Medical School, Hanover, N. H., 1896; aged 44; died at his home, September 24, from influenza.

Henry James Brugge, Grass Range, Mont.; Rush Medical College, 1897; aged 42; a member of the Medical Association of Montana; died, about October 20.

Lieut. Arthur Hastings Wheeler ⊕ **M. C., U. S. Army,** Albany, N. Y.; Albany (N. Y.) Medical College, 1912; aged 30; died in California, October 26.

Aurelius Augustine Lyon, Nashville, Tenn.; Washington University, St. Louis, 1861; aged 80; Confederate veteran; died at his home, November 6.

James Thomas Wadkins, Union City, Ga.; Chicago College of Medicine and Surgery, 1913; aged 36; died at his home, October 28, from influenza.

Charles A. Boyce, McLean, N. Y.; University of Syracuse, N. Y., 1879; aged 63; died in his home, November 12, from organic heart disease.

William H. Johnson, Barry, Ill.; Missouri Medical College, St. Louis, 1879; aged 63; died in Barry, November 7, from cerebral hemorrhage.

Theodore Lamkin ⊕ Bellamy, Ala.; Birmingham, Ala., Medical College, 1910; aged 39; died in Selma, Ala., October 28, from pneumonia.

Charles Edgar Walker ⊕ Charlotte, N. C.; University of Maryland, Baltimore, 1891; aged 51; died suddenly at his home, November 8.

Isaac W. Starr, Brownsville, Ore.; Willamette University, Salem, Ore., 1877; aged 64; died at his home, November 2, from heart disease.

Stanley Miller Martsolf ⊕ Westover, Pa.; University of Pittsburgh, 1902; aged 41; died in the Clearfield, Pa., Hospital, October 28.

Clifford Alfred Chance ⊕ Madrid, Iowa; Drake University, Des Moines, Iowa, 1911; aged 38; died at his home, recently, from pneumonia.

Patrick Joseph McNulty, Glenlyon, Pa.; University of Louisville, Ky., 1907; aged 42; died at his home, October 28, from influenza.

William Bray Warner ⊕ Red Bank, N. J.; New York University, New York City, 1882; aged 58; died at his home, September 1.

William Bowman, Marion, Ind. (license, Indiana, 1903); aged 70; died in a sanatorium in Indiana Harbor, Ind., November 6.

Howard H. Hopkins, New Market, Md.; University of Maryland, Baltimore, 1869; aged 70; died at his home, October 16.

Edgar L. Bay ⊕ Eddyville, Iowa; Marion-Sims College of Medicine, 1899; aged 45; died at his home, October 31, from influenza.

Robert Reginald Krueger ⊕ Vestaburg, Pa.; University of Pittsburgh, 1916; aged 29; died at his home, November 10.

James L. Brown ⊕ Peoria, Ill.; Medical College of Ohio, 1868; aged 77; died at his home, November 8.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

BEER AND CANCER CURES

Did the Brewing Interests Advertise Autolysin?

Our readers may remember that an article appeared in this department of The Journal for July 6, 1918, under the title "Henry Smith Williams and 'Proteal Therapy.'" "Proteal Therapy" is a treatment exploited by Henry Smith Williams, M.D., of New York, for use in tuberculosis, cancer, rheumatism, etc. It is apparently a modification of the "Autolysin" cancer "cure" which Williams had previously puffed in *Hearst's Magazine.*

The Journal's article pointed out that Henry Smith Williams, although entitled to write "M.D." after his name, is essentially a journalist. He has written voluminously for some years in lay publications on various subjects, both under his own name and under his *nom de plume,* "Stoddard Goodhue, M.D." In addition, Williams runs a publishing concern called the Goodhue Company, which issues a number of books, many of them being reprints of Williams' own articles.

Closely associated with Henry Smith Williams is his brother, Edward Huntington Williams, who also is a prolific writer. The Journal's previous article called attention to the fact that there had been sent broadcast to physicians a neat little cloth-bound book, entitled, "Alcohol, Hygiene and Legislation." This book, which evidently cost somebody a good deal of money to distribute gratis, was published by the Goodhue Company, and was written by Edward Huntington Williams. Enclosed with the book was an advertising leaflet on the "Autolysin" cancer cure and also a letter from the Goodhue Company, asking physicians to accept it "with our compliments and the compliments of the author." The letter was chiefly devoted to calling attention to Henry Smith Williams' "new book, the Autolysin Treatment of Cancer." The last thirteen pages of the book "Alcohol, Hygiene and Legislation" contained advertisements of the Goodhue Company's publications, particular emphasis being placed on the "Autolysin Treatment of Cancer," by Henry Smith Williams.

So much by way of retrospect. Now comes information that may throw an interesting side-light on the matter just presented. There is at present being conducted by a committee of the United States Senate, an investigation relative to the purchase of a Washington (D. C.) newspaper with money alleged to have been furnished by those interested in the brewing industry.

At the opening hearing before the Senate Committee, Tuesday, November 19, the secretary of the United States Brewers' Association, after admitting that brewers' propaganda had been published in the *International Monthly,* edited by Viereck (of the *Fatherland*), also declared that the Publication Committee of the brewers' association employed writers to "write up certain subjects" relating to the brewers' trade. One of the writers mentioned in this connection was, according to the newspaper reports, "Dr. Edward H. Williams, author of articles published in medical and other journals."

With this fact before us, it seemed worth while to go through the book that had been distributed so lavishly to physicians with the compliments of the Goodhue Company and Dr. Edward Huntington Williams, in the exploitation of "Autolysin," and Henry Smith Williams' book on the subject.

The first chapter of "Alcohol, Hygiene and Legislation" consists of a reprint of an article from the *New York Medical Journal* of May 8, 1915. The article is a skilful presentation of the case for the defenders of the lighter alcoholic beverages, especially beer. This chapter and all succeeding chapters of the book attempt to discredit prohibitory legislation, and argue that prohibition drives the public to the use of the more ardent alcoholic beverages, while preventing the use of the milder beverages, such as beer, which one is led to infer is not particularly harmful. Throughout the book, also, the state of Kansas is held up as an example of the harm done by prohibition, and the theme is developed that insanity and the use of cocain and other habit-forming drugs follows in the wake of prohibition. The following extracts are from Chapter I:

> The evil effects of *beer* and wine, for example, are greatly less than those produced by spirituous liquors. . . . [Italics ours.—ED.]
>
> If our theory of immunity is correct we should expect to find that the older beverages, such as *beer* and wine, which have been used for thousands of years, are less productive of alcoholic insanity, for example, than the spirituous liquors which are recent innovations. In point of fact we find this to be the case: the spirituous liquors are almost wholly responsible for all forms of alcoholic insanity. [Italics ours.—ED.]

Chapter II is a reprint of an article that appeared in *Everybody's Magazine*, August, 1914, and deals with "Legislation from a Medical Viewpoint." It is to the effect that drug addictions and insanity, together with special forms of mental diseases directly attributable to alcoholism, seem to flourish best in prohibition territory.

Chapter III deals with "The Peace and War Footing of Alcohol," and is a reprint from the *Medical Record*, Aug. 7, 1915. It, too, sings the praises of the "lighter beverages," while deprecating the use of "ardent spirits." For instance:

> An overwhelmingly large proportion of persons who develop alcoholic psychoses in America are drinkers of whisky, or some corresponding ardent spirit, whereas this condition is seldom seen in *beer* and wine drinkers. [Italics ours.—ED.]
>
> Thus we find the highest percentage of alcohol psychoses among the whisky-drinkers who come from western Europe, while the wine and *beer* drinking races of central and southern Europe show a distinctly lower percentage, in some instances only about one-fourth as many per thousand. [Italics ours.—ED.]

Chapter IV deals with "Some Aspects of Liquor Legislation." Like Chapter II it is an indictment of prohibition, and the United States Census Bureau's reports are called on to sustain this thesis. Quotations, too, are made from the writings of Henry Smith Williams further to prove the point. "Dry" Kansas and "wet" Nebraska are frequently compared, to the detriment of the former. One who accepts the statements in this chapter will get the impression that Kansas has more lawlessness, illiteracy, pauperism, and insanity than Nebraska.

Chapter V deals with "The Problem of Legislation." It is based on the premise that "prohibition does not prevent the consumption of liquor," but on the contrary, "prohibitive legislation induces the consumption of the most harmful form of liquors." Stated in another way, it is equivalent to charging that prohibition is hard on the brewers, but beneficial to the distillers. In fact, E. H. Williams, in another book ("The Question of Alcohol"—Goodhue Co.) which also champions the case for the milder alcoholics, quotes Henry Smith Williams as saying, relative to prohibitory legislation: "In general, it would appear that, if our legislators of recent years had been in league with the distiller, they could not have served his purpose better."

Whether or not Edward H. Williams' or Henry Smith Williams' conception of the alcohol problem is good, bad or indifferent, need not at this time concern us. The medical profession, however, has a right to ask two questions: First, Is the Dr. Edward Huntington Williams who wrote "Alcohol, Hygiene and Legislation" the "Dr. Edward H. Williams" who was employed by the brewers to write propaganda favorable to the brewing interests? Second, Was the cloth-bound book, "Alcohol, Hygiene and Legislation," which was distributed by the Williams brothers, paid for, wholly or in part, by the United States Brewers' Association?

For those who wish to read Dr. Edward Huntington Williams' opinions on the alcohol question, the following bibliography may be of service:

"Liquor Legislation and Insanity": *Medical Record*, 1913, lxxxiv, 791.
"The Liquor Question in Medicine": *Medical Record*, 1914, lxxxv, 612.
"Inebriety as a Medical Problem": *Post-Graduate*, 1914, xxix, 603.
"The Problem of Inebriety": *N. Y. Medical Journal*, 1915, ci, 940.
"Aspects of Inebriety in Alcohol": *British Journal of Inebriety*, 1915-1916, xiii, 9.
"The Peace and War Footing of Alcohol": *Medical Record*, 1915, lxxxviii, 226.
"Alcohol and Therapeutics": *Medical Record*, 1917, xcii, 666.

Correspondence

A PRELIMINARY REPORT OF A STUDY OF THE COAGULABILITY OF INFLUENZAL BLOOD

To the Editor:—During the recent influenza epidemic, one of the most striking symptoms was an almost constant occurrence of hemorrhage. Nosebleed was present nearly always in children, and often in adults. Some of the women had menorrhagia and metrorrhagia, and abortion was frequent. We observed one case with hemorrhage from the bladder and two with hemorrhage from the bowels. The cerebrospinal fluid contained blood in two cases in which lumbar puncture was performed for a suspected meningitis. Bleeding from the gums was common, and several young patients developed hemorrhagic purpura. A majority of the so-called pneumonia patients coughed up bright red blood, some of them dying suddenly from asphyxiation due to active hemorrhage. Sudden death came to one convalescent patient from what was, clinically at least, a hemorrhage in the brain.

The regularity with which these various hemorrhages appeared suggested the possibility of there being a change in the blood itself, and accordingly we tested the coagulation time of blood taken from a large number of influenza and pneumonia patients. In every case tested, without a single exception, the coagulability of the blood was lessened, the increase in time required for coagulation varying from two and one-half to eight minutes more than the normal. Blood was tested as early as the second day of influenza, and as late as the twentieth day of convalescence from pneumonia, with the same results. A sufficient number of controls were tested to establish the normal coagulation time for the tests used. Several local physicians also tested blood from their patients, and, while our records are at this time necessarily incomplete, we have yet to receive a report of a case in which the time of coagulation was not prolonged.

With a view toward lessening the tendency to hemorrhage, we started the early use of large doses of calcium lactate, which apparently gave good results. There also seemed to be less bleeding in the pneumonia patients who took calcium iodid to control their cough. We arrived at our conclusions too late in the epidemic to try horse serum or similar coagulating agents, but we believe that in a certain type of pneumonia, or what would be better called hemorrhagic bronchitis, their use would have been justified.

We have no theory to account for the increased coagulation time of influenzal blood. Possibly the presence of *Streptococcus hemolyticus* may be responsible; but as the lessened coagulability appears early while the red cell count remains nearly normal, it would seem that the first change is in the serum rather than in the corpuscles.

We submit this incomplete report in the hope that others may be sufficiently interested in this apparently overlooked feature of influenza to check our findings.

A. W. ERSKINE, M.D., and B. L. KNIGHT, M.D.,
Cedar Rapids, Iowa.

ROENTGEN FINDINGS IN THE PNEUMONIAS FOLLOWING INFLUENZA

To the Editor:—The roentgen examination of the chests of influenza patients during the recent epidemic revealed some very interesting conditions. The cases were not selected to any great extent. The diagnosis of pneumonia, as a rule, was made clinically, and the roentgen ray was used only as corroborative evidence and to determine the extent of involvement. The striking feature was the apparent difference in opinion as to the type, whether lobar pneumonia or bronchopneumonia.

When seen early, the patients presented a rather marked peribronchial infiltration of the larger trunks, with a local or general mediastinitis. The lung structure appeared normal and the movements of the diaphragm were unimpaired. This pathologic condition either became stationary with a corresponding improvement in the clinical symptoms or there was a rapid progression out into the lung structure with the development, as a rule, of a bronchopneumonia.

In a few instances, the pneumonia was lobar, being confined to one or more lobes. In some cases the infection was so severe that a general pulmonary edema developed with almost complete obliteration of the normal chest shadows. Associated with this severe pulmonary edema was an effusion into the pericardial sac. In examining these cases roentgenographically an attempt was made to follow the regular routine, which consisted of fluoroscopy first, and then the making of plates. Some patients were so very ill that only a minimum amount of observation could be attempted. On fluoroscopy in the mild cases one was struck with the density of the hilum shadows and the marked infiltration of the larger bronchi with an increase in the mediastinal density. In these cases the movements of the diaphragm were unimpaired. In the definite pneumonias the findings would be as above with a bronchopneumonia involving both lungs, as a rule, although a number of cases of unilateral bronchopneumonia were observed.

In these cases the movements of the diaphragm were unimpaired unless the infection was very extensive. These cases at times were so severe that the entire chest became involved, with here and there small islands of apparently normal lung tissues. It was remarkable to see these patients and wonder how they could possibly breathe. A great number of cases of lesser severity were noted. Those that were definitely lobar pneumonia showed involvement of one or more lobes, usually beginning in the lower right. They appeared to be less toxic and were easier to handle. The respiratory movements were always rapid, and the movements of the diaphragm on one or both sides were impaired, and frequently fluid was found in the pleural cavity.

This type of pneumonia was the exception. In these conditions the heart was of interest. In the severe cases of pulmonary edema the heart shadow was obscured, owing to the edema and the fluid in the pericardial sac. A number of hearts in the bronchopneumonia types appeared distinctly bottle shaped. On repeated observations this was found to be due, not to fluid in the pericardial sac, but to a degeneration of the heart muscle with dilatation. In the lobar pneumonias the heart was found, as a rule, enlarged, and was a striking feature along with the impairment of the movements of the diaphragm.

Multiple abscess formation in the lobular type and empyema in the lobar type were also observed, although the latter was not nearly so frequent as in the pneumonias of last fall. Another feature worthy of note was the apparent similarity of these bronchopneumonias to the findings in an acute pulmonary tuberculosis. It would be impossible from roentgen examination alone to differentiate these cases, even after apparent recovery from the pneumonia.

It is with a great deal of hesitancy that we should diagnose cases of tuberculosis in individuals who have had influenza or influenzal pneumonia, even months after apparent recovery. In a limited number of cases bronchiectasis was noted, nearly always unilateral and mostly confined to the lower right chest.

Harry F. Friedman, M.D., Chelsea, Mass.
Lieutenant, Junior Grade, U. S. N. R. F.; Roentgenologist,
U. S. Naval Hospital.

"STUDIES OF ROENTGENOGRAMS OF THE ACCESSORY NASAL SINUSES"

To the Editor:—In The Journal, Nov. 9, 1918, p. 1555, Dr. Max Unger of New York, in a preliminary note, describes an alleged new method for the study of the nasal accessory sinuses with the roentgen rays.

As a matter of fact, this method was described very accurately by Dr. George E. Pfahler of Philadelphia, in an article published in the *Laryngoscope*, July, 1916. Every detail mentioned by Dr. Unger appears in Dr. Pfahler's original paper, with considerable enlargement. The only variation in the method consists in the exact size of the film that is used. Dr. Pfahler even described the possibility of cocainization of the pharynx in some hypersensitive patients. He also mentioned the advantages of the method in studying the relations of the floor of the antrum to the neighboring teeth.

Since the publication of this method by Dr. Pfahler, it has been used very generally by roentgenologists throughout the country. I myself have employed it several times.

The method is mentioned on page 208 of Knox's "Radiography," second edition.

Dr. Unger states that his report is a preliminary one and deals only with the use of this method on the cadaver. Yet this is a method that has been in general use on living patients for some time.

Isaac Gerber, M.D., Providence, R. I.

[A proof of the preceding was sent to Dr. Unger, who replies:]

To the Editor:—I wish to acknowledge with chagrin that Dr. Gerber is correct. My claim to originality was made in good faith since a roentgenologist with whom I discussed the method knew nothing of it and the literature consulted did not contain it. I missed the line in Knox's "Radiography" that mentions this method. May I congratulate Dr. Pfahler on devising such an excellent method.

Max Unger, M.D., New York.

SPENCER'S CHLORAMINE PASTILLES

To the Editor:—I notice on the market in local drug stores an article made by "John Wyeth & Son, Sole Proprietors, Philadelphia," labeled "Spencer's Chloramine Pastilles" and recommended for "influenza" and other (similar) conditions. It is further stated that "as the name indicates," these pastilles are made up of *ammonium chlorid* and other substances (which are named), and contain opium.

In view of the fact that "chloramin" is the accepted name of p-toluene sulphochloramid, and that this substance has been recommended for use as a throat spray in connection with the present epidemic of influenza, it seems as though the "chloramine pastilles" were likely to deceive the public, and result in greater, rather than less danger to the people who do not know the nature of these substances, or their relative value.

Should not this be called to the attention of the medical profession, and if possible, of the general public?

S. C. Brooks, Boston.

[Comment.—The term "chloramin" is applied to a class of chemical compounds that contain group :NCl. The chloramin derivative sodium paratoluenesulphochloramid has been called chloramin-T, the "chloramin" indicating the characteristic NCl group, and the "T" the derivation from toluene. Sodium parabenzenesulphochloramid has been called chloramin-B, the "B" indicating its origin from benzene. Before chloramin-T and the related products came into use in medicine, John Wyeth and Brother had registered the term "chloramine" as a trademark for a pharmaceutical preparation which in no sense is a chloramin. This misuse of a chemical term is to be regretted, and indicates the need for a revision of our trademark law which permitted the registration of this evidently misleading term.—Ed.]

Native Customs and Cancer.—In parts of China where the head is shaved by public barbers, the razors used are often dull and full of nicks, and the irritation of this scraping often causes cancer. Chinese men suffer from cancer of the pharynx and esophagus due to their habit of eating very hot rice, which is thrown into the mouth forcibly with chop sticks. Chinese women eat after their lords and masters, when the rice is cold, and they never have this kind of cancer. In India much cancer is caused by the chewing of betel nut. In some parts of the country women do not chew the nut, and are free of cancer of the mouth. In Khurdistan, India, the natives wear baskets filled with hot coals across their abdomens to protect them from the cold, and more than 50 per cent. of all the cancer in that region forms in the abdomen and groin, while in other countries such cancers are very rare.—Major W. J. Mayo, War Department Lectures.

COMING EXAMINATIONS

Alabama: Montgomery, Jan. 14. Chairman, Dr. S. W. Welch, Montgomery.

Arizona: Phoenix, Jan. 7. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

Colorado: Denver, Jan. 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Delaware: Wilmington, Dec. 10-12. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

District of Columbia: Washington, Jan. 14-16. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

Florida (E): Jacksonville, Dec. 16-17. Sec., Dr. G. A. Munch, 1806 Franklin St., Tampa.

Florida (R.): Miami, Dec. 2-3. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Hawaii: Honolulu, Jan. 6. Sec., Dr. J. R. Judd, Honolulu.

Illinois: Chicago, Dec. 9-11. Mr. F. C. Dodds, Supt. of Registration, Springfield.

Iowa: Des Moines, Dec. 10-12. Sec., Dr. G. H. Sumner, Capitol Bldg., Des Moines.

Louisiana: New Orleans, Dec. 2-4. Sec., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Minnesota: Minneapolis, Jan. 7-10. Sec., Dr. Thomas McDavitt, 741 Lowry Bldg., St. Paul.

New Mexico: Sante Fe, Jan. 13. Sec., Dr. W. E. Kaser, East Las Vegas.

North Dakota: Jan. 7. Sec., Dr. G. M. Williamson, 860 Belmont Ave., Grand Forks.

Ohio: Columbus, Dec. 3-5. Sec., Dr. H. M. Platter, State House, Columbus.

Oklahoma: Oklahoma City, Jan. 7-8. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, Jan. 7. Sec., Dr. H. S. Nichols, Corbett Bldg., Portland.

Pennsylvania: Philadelphia, Jan. 7-9. Sec., Mr. Nathan C. Schaeffer, State Capitol, Harrisburg.

Rhode Island: Providence, Jan. 2-3. Sec., Dr. B. U. Richards, State House, Providence.

South Dakota: Pierre, Jan. 14. Sec., Dr. P. B. Jenkins, Waubay.

Utah: Salt Lake City, Jan. 6. Corres. Sec., Dr. G. F. Harding, 405 Templeton Bldg., Salt Lake City.

Virginia: Richmond, Dec. 10-13. Sec., Dr. J. W. Preston, 215 S. Jefferson St., Roanoke.

Washington: Spokane, Jan. 5. Sec., Dr. C. N. Suttner, 415 Old Nat'l Bk. Bldg., Spokane.

Wisconsin: Madison, Jan. 14. Sec., Dr. J. M. Dodd, 220 E. 2d St., Ashland.

California June Examination

Dr. C. B. Pinkham, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at San Francisco, June 25-27, 1918. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Of the 166 candidates who took the physician's and surgeon's examination, 125, including 25 osteopaths, passed, and 41, including 32 osteopaths, failed. Two candidates were licensed on Army and Navy credentials. Fifty-two candidates were licensed through reciprocity and 3 candidates were granted osteopathic reciprocity licenses. Of the 9 drugless healers examined, 8 passed and 1 failed. Ten candidates were granted licenses to practice chiropody. The following colleges were represented:

PASSED

Iowa September Examination

Dr. G. H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, Sept. 10-12, 1918. The examination covered 8 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 9 candidates examined, 8 passed and 1 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Howard University	(1918)	77.1
Bennett Medical College	(1914)	88.6
Northwestern University	(1918)	79.2, 86.2
Rush Medical College	(1918)	91.1
University of Illinois	(1918)	88.2

Nebraska June Examination

Dr. J. J. Hompes, secretary of the Nebraska State Board of Medical Examiners, reports the oral, practical and written examination held at Lincoln, June 3-5, 1918. The examination covered 14 subjects. An average of 75 per cent. was required to pass. Of the 45 candidates examined, 44 passed and 1 failed. Twenty-one candidates were licensed through reciprocity. Four candidates were granted reregistration certificates. The following colleges were represented:

Oklahoma July Examination

Dr. J. J. Williams, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, July 9-10, 1918. The examination covered 10 subjects and included 100 questions. An average of 70 per cent. was required to pass. Six candidates, including 1 osteopath, were examined, all of whom passed. Sixteen candidates, including 7 osteopaths, were licensed through reciprocity. Seven candidates were granted reregistration licenses. The following colleges were represented:

College — PASSED	Year Grad.	Per Cent.

Book Notices

DISPENSARIES: THEIR MANAGEMENT AND DEVELOPMENT. A Book for Administrators, Public Health Workers, and All Interested in Better Medical Service for the People. By Michael M. Davis, Jr., Ph.D., Director of the Boston Dispensary, and Andrew R. Warner, M.D., Superintendent of Lakeside Hospital, Cleveland. Cloth. Price, $2.25. Pp. 438. New York: The Macmillan Company, 1918.

The first dispensary in this country was started in 1786. What a difference between that primitive institution, managed entirely by one charitably inclined doctor dispensing drugs to perhaps sixty or seventy poor persons during the year, and the great modern dispensary with its scores of employees and its large medical staff, representing all departments of the science, and handling hundreds of patients daily. From a single little room, or perhaps only a desk, in the back of an apothecary shop, the dispensary has grown until it has become one of the largest and most important factors in present day social economics. How this growth has taken place and the various factors that have been instrumental in bringing the dispensaries up to their present high state of development have been most interestingly and instructively presented by the authors in this volume. They likewise discuss in a comprehensive manner the proper management of modern dispensaries, from the small dispensary handling only a few cases daily, or the special dispensary with but a single class of cases, to the great general dispensary, with its many clinics, handling 100,000 or more cases annually. Every phase of the subject, including the financing of such institutions, the question of free and pay patients, efficiency tests, the follow-up system, and social service in all its departments, is covered in a very thorough manner. Not only physicians but those laymen who are interested in the great problems of public health will find in this excellent volume much that is of interest and also of great value.

HYGIENE OF THE EYE. By William Campbell Posey, A.B., M.D., Ophthalmic Surgeon to the Wills and Howard Hospitals. Cloth. Price, $4 net. Pp. 344, with 120 illustrations. Philadelphia: J. B. Lippincott Company, 1918.

This volume contains twenty chapters treating of the ocular structures; visual physiology; refraction and glasses; strabismus; the influence of diseased eyes on the body; school life; artificial and natural lighting; school architecture; the most noticeable diseases of the eye; wounds and injuries; the effects of drugs and beverages on the eyes; color blindness; what to do for the blind; conservation of vision, etc. It is well written and produced. The author's name is a sufficient guarantee of its scientific quality. In paper, printing, etc., it is a physical demonstration of how books may be produced and read with as little injury to the eye as possible. The volume is hardly written for specialists, but it will be found an exceedingly useful book for general practitioners who wish to review the subject and become familiar with facts they should know about the eye. It will also be an extremely valuable book for those members of the laity who desire to keep in touch with this important subject. It can be especially recommended to teachers, nurses, and those who direct hygienic conditions of shops, factories, etc.

GYMNASTIC TREATMENT FOR JOINT AND MUSCLE DISABILITIES. By Brevet Col. H. E. Deane, R. A. M. C. In Charge War Hospital, Croydon. With Preface by Temp. Colonel A. Carless, Army Medical Service and Brevet Lieut.-Col. F. W. Mott, F.R.S., R. A. M. C. (T.) Maudsley Hospital, Denmark Hill. Cloth. Price, $2.50 Pp. 146, with illustrations. New York: Oxford University Press, 1918.

In this little book the author sketches his method of gymnastic treatment of joint and muscle disabilities among wounded soldiers, employing apparatus of the simplest sort, and having in view always the quickest possible return of the man to his military duties or, if permanently invalided, to the best possible working and earning condition. While giving due credit to massage, passive motion, either manual or mechanical, he deprecates the prolonged keeping of these patients under such treatment, and insists that much time is wasted; frequently the patient is hospitalized and allowed to deteriorate, when by proper gymnastic methods not only is he educated in the "will to do" for himself, but practical and remarkable improvement is quickly arrived at by the method he teaches. Every detail of the gymnastic methods employed should be familiar to the one who attempts to apply them. They are simple but effective. The author says that "all the apparatus necessary to cultivate any movement which a soldier is likely to want, and on which work can be adjusted to suit any man fit for exercise at all, are a skipping rope, Indian clubs, dumb-bells, a beam, a slanting ladder, a sparred plank, parallel bars, wall bars, ropes and a nautical wheel," all of which apparatus in use are pictured in the book. The principle constantly emphasized is to have the patient do something for himself, employing the simple apparatus named, together with other calisthenic and gymnastic movements, games, etc., aiming at perfect anatomic results, but being satisfied with compensatory movements, in some cases, that are practically as good.

The Doctor's Part: What Happens to the Wounded in War. By James Robb Church, A.M., M.D., Colonel, Medical Corps, U. S. Army. With Foreword by Major-General William C. Gorgas, Surgeon-General, U. S. Army. Boards. Price, $1.50 net. Pp. 284, with illustrations. New York: D. Appleton and Company, 1918.

It is a pleasure at these times to read a book that describes the care of the wounded in France without emotion or sensationalism. Colonel Church is well prepared to write such a book. He has served for twenty years in the Army. In the war with Spain he was with the rough riders, and won the medal for gallantry under fire. He also served on the Mexican border. Early in 1915 he was sent to France as medical military observer. As such he was admitted to the inner medical circles everywhere, and was even able to get into the front trenches. He writes, therefore, as one who speaks with knowledge gained from actual observation and from personal experience. The work amounts to a description of the physician's part in the care of the wounded from the trench and battle field to the first-aid station on through the field, evacuation, base, general and special hospitals. One might suppose that such matter would make tedious reading; but Colonel Church has the happy faculty of making an interesting story out of what might ordinarily be regarded as a dry subject, especially by laymen. Interspersed all along are little incidents and stories of human interest, amusing episodes and withal glimpses of tragedies. His descriptions of conditions met with—of the hospitals, of the physician's life at the front, etc.—are graphic and illuminating. The book is written for the layman in nontechnical language, but certainly this does not detract from its interest for physicians. Colonel Church has a distinct literary touch of which few physicians can boast. Thus he has put life into a dry subject and the result is a book full of information of practical value that is as interesting to read as a novel.

The American Hospital of the Twentieth Century. A Treatise on the Development of Medical Institutions, Both in Europe and in America, Since the Beginning of the Present Century. By Edward F. Stevens, Architect. Cloth. Price, $5. Pp. 274, with illustrations. New York: Architectural Record Publishing Company, 1918.

The author, an architect, devotes his time exclusively to hospital construction, and has compiled an interesting book showing the rapid developments in hospital planning and construction in this country. He pictures and describes many of the world's greatest hospitals abroad as well as hospitals of every size and specialty in this country, the final chapter being concerned with military hospitals of the present war. The book is profusely illustrated. In the period of construction and reconstruction that will now take place, works of this character should be of great service to those planning new medical institutions.

Diseases of the Heart: Their Diagnosis, Prognosis, and Treatment by Modern Methods, with a Chapter on the Electro-Cardiograph. By Frederick W. Price, M.D., F R.S., Physician to the Great Northern Central Hospital, London. Cloth. Price, $7.50. Pp. 472, with 246 illustrations. New York: Oxford University Press, 1918.

The object of this book as stated in the preface is to include information with regard to recent advances in the study of cardiac disorders, as well as an account of our knowledge prior to this; and by discussing both from the point of view of the clinician, to enable the medical practitioner to take the fullest possible advantage of modern methods in the diagnosis, prognosis and treatment of diseases of the heart. This purpose has been as well accomplished as could be expected in a volume of 436 pages of text. About one half is taken up with a consideration of the more modern aspects of cardiology, such as the newer conceptions of the irregularities, the polygraph and the electrocardiograph. An intimate familiarity with these subjects is revealed and the topics are well handled. The same may be said of the discussion of the so-called older or better known diseases of the heart, such as the valvular lesions, and diseases of the myocardium, pericardium, etc. The author has the knack of crowding a good many facts into small space so that the book is really a reliable condensed compendium of knowledge of heart disease. Many polygraphic and electrocardiographic tracings elucidate the text.

Social Medicine, Medical Economics and Miscellany

The Stimulating Effect of Nutrients

F. G. Benedict and T. M. Carpenter in Publication 261 of the Carnegie Institution of Washington (1917) give the results of an extensive series of observations with human subjects on the influence of the ingestion of food on metabolism, with special reference to the stimulating effect of nutrients. The conclusions drawn from the various groups of experiments have been stated by the authors in abstracts as follows: (1) The work of mastication, such as would be involved in chewing gum or a rubber stopper continuously, may require an increment in the heat production of approximately 17 per cent. (2) The ingestion of water with a temperature of either 22 C. or 55 C. produces no significant increment of the basal metabolism, if not over 500 gm. of water are taken. With larger amounts of cold water there may be an increase which, in certain instances, has been found to amount to 16 per cent. above the basal value. (3) Coffee, owing probably to its caffein content, acts as a stimulus to the metabolism. Approximately 325 gm. of coffee at a temperature of about 60 C. will produce an increment in the metabolism of 8 to 9 per cent. (4) Beef tea, taken either hot or cold, slightly increases the metabolism. (5) With carbohydrates the basal metabolism may be increased to an average maximum of approximately 25 per cent. by the ingestion of 100 gm. of any one of several sugars, although levulose and sucrose appear to exert a somewhat more powerful influence than the other sugars. This increment occurs inside of two hours and the metabolism has a tendency to return to the base line somewhat rapidly thereafter. (6) The ingestion of a diet containing a preponderance of fat produces a positive increment in the metabolism, although this increment is considerably less than that observed with an equivalent amount of energy in either carbohydrate or protein. (7) The ingestion of protein in almost any quantity invariably produces an increase over the basal heat production, which may be 25 per cent. for several hours, and for short periods may rise to 45 per cent. No definite mathematical relationship between the amount of protein ingested and the increment in the total metabolism could be established in these experiments. No clearly defined difference between the animal and vegetable proteins was found in their influence on the metabolism. (8) The experiments with mixed diets, especially those with excessive amounts of food, showed that it was possible by the ingestion of a large meal to stimulate the metabolism to 40 per cent. above the basal value for a number of hours, and to 20 per cent. for at least eight hours; indeed, there was every reason to believe that the stimulus to the metabolism would have been found to continue considerably longer than the experimental period of eight hours if the observation had been prolonged. The "cost of digestion," or the mathematical relationship between the fuel value of the intake and the increase in heat production due to the ingestion of food, is estimated with carbohydrates to be not far from 6 per cent. on the average; with fat the increase is about 2 per cent. of the fuel value of the intake, with a protein-rich diet approximately 12 per cent., and with mixed diets 6 per cent.

Medicolegal

Quarantine of Communicable Diseases [*]

A decision by the supreme court of the State of Washington, Aug. 27, 1918, in effect prohibits the release on habeas corpus of a person detained in quarantine by order of the boards of health of Seattle and the state. This person, arrested for disorderly conduct, had been examined by the health commissioner of Seattle in accordance with an ordinance, found to have syphilis, and sent, in accordance with another ordinance, to an isolation hospital for detention and treatment. He had appealed to the state board of health as provided by law, but the finding of the commissioner had been affirmed. He then petitioned the state supreme court for a writ of habeas corpus, and the superior court for King County was instructed by the latter to inquire into the time and cause of his detention. The superior court issued an order to have him examined before it, and thereupon the health commissioner applied to the supreme court for a writ restraining further proceedings on the ground, among others, that an order of the health commissioner could not be reviewed by the court.

The detained person contended that to deny him such a review was to suspend the writ of habeas corpus, and that the actions and findings of boards of health were open to judicial inquiry the same as other boards, institutions and officers. Bailey (Habeas Corpus, Sec. 106) was quoted to the effect that the determinations of such boards "are not final and conclusive; if they were, then the exercise of such summary power could not be upheld."

In its decision the supreme court states that to follow Bailey would be to make the exercise of the police power a judicial function and holds that:

> A writ of habeas corpus is a writ of right, and is never to be denied in any case where the liberty of the subject is made the subject of inquiry. But it has always been held that a return showing a legal cause for the detention of a petitioner is enough to suspend the operation of the writ. . . . Where the police power is set in motion in its proper sphere, the courts have no jurisdiction to stay the arm of the legislative branch of the government, for it is operating in its own particular field, where even the courts are powerless to insist upon a procedure consistent with the forms of the common law. Some courts have held that the discretion and judgment of administrative officers, while very broad, is not absolutely and in all cases beyond judicial control, but the tendency is away from this doctrine, for, granting the right to question means and methods in one case, the questions of fact upon which the administrative order is based might be raised in every case, and the object of the law, which is to deal summarily, to the end that imminent peril to the public may be averted, would be wholly overcome. At any rate, a somewhat extended exploration of the books convinces the writer that a court should not inquire into the reasonableness of an ordinance sounding in the police power in any case where the legislative body has provided the means and methods of carrying it out.

In substantiation of this view, the court cites previous decisions by the Washington Supreme Court and a number of decisions by the United States Supreme Court in regard to the examination or quarantine of immigrants, one of the latter holding that:

> Where a statute gives a discretionary power to an officer, to be exercised by him upon his own opinion of certain facts, he is made the sole and exclusive judge of the existence of those facts, and no other tribunal, unless expressly authorized by law to do so, is at liberty to reexamine or controvert the sufficiency of the evidence on which he acted.

Some additional points were raised by counsel in the case, notably the question of the constitutionality of the quarantine law, which leaves to the boards of health definitions and classification of diseases to be quarantined. In regard to this point the supreme court said:

> This court has not heretofore considered similar laws as a delegation of legislative power or authority. The legislation is that of the legislative body, but it is not always practical to meet every phase of the necessity that has called for the law by the enactment of a general statute. . . . Nor is there any legal reason for denying the power to quarantine summarily, or to restrain for treatment, a citizen or subject because the authority may be abused or the law maladministered in a given case.

One of the points made by the commissioner was that he could not bring his ward into court for examination without subjecting himself to the penalties of the quarantine law; but the supreme court held that "if the court has jurisdiction to inquire into the cause of his detention, resort to examination and expert opinion by those skilled in the diagnosis of disease would not be a breaking of the quarantine."

The contention of the detained person, that the city of Seattle had no authority to pass health ordinances or to create the office of health commissioner, was overruled by the supreme court.

Presumption as to Fit Condition of Person to Use Bath

(Warren v. Werther (N. Y.), 169 N. Y. Supp. 709)

The Supreme Court of New York, Appellate Division, First Department, in reversing a judgment that was rendered in favor of the plaintiff for damages for burns sustained after he became unconscious in the hot room in taking a Turkish bath, but without any negligence on the part of the defendant being proved, holds that when a person apparently in good health and condition presents himself for the use of the accommodations provided in a public bath, the proprietor thereof is justified in believing that the patron is in fit condition to use the bath, knows what he is about, and can safely be permitted to make use of the bathing privileges as ordinarily conducted. The contention that the defendant was liable for failure to supply the plaintiff with medical attendance, after the accident, the court answers by saying that there was no proof in the case that the injuries were in any way aggravated by the tardiness of the medical attendance, nor in fact did the record justify even an inference that the plaintiff was not furnished with medical attendance as soon after he was removed from the hot room as was possible.

Representations of Physicians Making Releases Voidable

(Althoff v. Torrison et al. (Minn.), 167 N. W. R. 119)

The Supreme Court of Minnesota, in affirming an order denying a motion made by defendant Torrison for judgment or a new trial after a verdict had been rendered in favor of the plaintiff for damages for personal injuries from having been struck by an automobile belonging to the defendant and driven by one of his employees, holds that the plaintiff was not barred from maintaining this action by a release executed on what might be taken as mistaken and misleading representations by physicians.

The court says that if agents or physicians in the employ of the defendant procure a release by intentionally deceiving the plaintiff and causing him to believe that his injuries are trivial when they are known to be serious, the plaintiff is not bound by such release.

If the plaintiff executed the release in reliance on representations as to the character and extent of his injuries, made for the purpose of inducing a settlement by agents or physicians employed by the defendant, and such representations were not true, he may avoid the release although the representations were made in good faith and with no intent to deceive; for they had the effect of causing him to be deceived as to a present existing fact—the character and extent of his injury—and amounted to a fraud in law notwithstanding the good faith of those making them. But if the information given to the plaintiff concerning the nature and extent of his injuries was correct and he was not misled as to the consequences which ordinarily follow from such injuries, the fact that an opinion as to the duration of his disability, honestly given, turns out to have been erroneous is not a sufficient ground for avoiding the release.

There was no error in a charge of the trial court which permitted the jury to disregard the release and return a verdict for the plaintiff in this case if they found that she had been induced to execute the release by fraudulent misrepresentations concerning the injury to her leg, or if they found that she had sustained an injury to the sacro-iliac joint which by mutual mistake had not been taken into account when the settlement was made. Conceding that the physicians acted in good faith in stating that they found the leg normal except for certain bruises, yet the evidence would justify the jury in finding that they were mistaken, and that the plaintiff had been misled by them into believing that the injuries to her leg consisted only of these bruises when in fact they included an injury to the nerves quite different in character and effect from what the bruises were represented to be. In other words, the evidence would justify a finding that they had not merely erred in an opinion as to the probable duration of the disability, but, although not intending to do so, had in fact misled the plaintiff as to the character and extent of the injury to the leg—an existing fact susceptible of knowledge.

---

[*] Reported in 3 Washington Decisions 297. From Public Health Reports, Oct. 4, 1918, p. 679.

The money received by the plaintiff having been expended in payment of doctor bills before she learned of the injury which caused her permanent disability, her failure to return it did not operate as a ratification of the settlement. The jury were properly instructed to apply it in reduction of damages if they found that she was entitled to recover them.

Construction of Law Giving Employer Right to Require Necropsy

(Indianapolis Abattoir Co. v. Bryant (Ind.), 119 N. E. R. 24)

The Appellate Court of Indiana, Division No. 2, says that this was the first case in that state, and no foreign case was called to the court's attention, and it found none, involving the construction of a similar statutory provision to that of Section 27 of the Indiana Workmen's Compensation Act, which reads, "The employer, or the industrial board, shall have the right in any case of death to require an autopsy at the expense of the party requiring same." The purpose of the lawmaking body in enacting such statute was, no doubt, for the protection of the employer, against unjust claims, particularly against the payment of compensation when death is due to natural causes instead of by accident. This court does not believe that it was the intention of the legislature that a necropsy could be demanded in every case of death. Such a construction would render the provision unreasonable when the cause of death is clearly apparent without it, when the cause of death is not uncertain and is not in dispute. The right to a necropsy is to be exercised with caution. It is one calculated under the most favorable circumstances to cause some distress of mind to the family of the deceased.

This was a proceeding under the workmen's compensation act to obtain compensation for the death of an employee of the abattoir company named Bryant, who left the claimant surviving him as his sole and only dependent. There was a dispute in this case as to the cause of the employee's death, and under the construction of the statute herein declared the employer had the right, if properly exercised, to have a necropsy performed. But when, as here, the legislature has not provided the procedure for its enforcement, that adopted must be reasonable both as to the time and the occasion for its exercise.

The court thinks that, when a representative of the company called on the claimant in the afternoon of the day following the death of the employee, after the body had been embalmed, and apparently without having with him any physician or any one to perform the work, and requested a necropsy, it could not be said that there was an unequivocal refusal to grant the right conferred by statute, because the claimant said she did not want a necropsy, unless it was absolutely necessary, but to have the man who sent the representative come and she would talk to him. The court also says that it will be observed that the statute in question makes no provision for making a necropsy further than the mere grant of the right, and provides no penalty or condition in case the claimant refuses to consent to it. Neither can it be implied from the statute as a whole that the legislature intended any penalty to follow a refusal. In the court's judgment, the refusal of a claimant to consent to a necropsy would not deprive the industrial board of jurisdiction to proceed to a final disposition of the case. Moreover, the right to demand a necropsy was a right that could be waived, and was waived by the employer's failure to follow up its request in some manner. Wherefore the award of the industrial board is affirmed.

Public Policy with Regard to Marriage of Epileptics

(Kitzman v. Kitzman et al. (Wis.), 166 N. W. R. 789)

The Supreme Court of Wisconsin holds that where, on Sept. 27, 1915, a man and a woman went from Wisconsin to St. Paul, Minn., there obtained a license to marry, and before a justice of the peace in the state of Minnesota had a marriage ceremony performed, receiving from the justice a marriage certificate in the proper form, and returning on the same day to Wisconsin, where they thereafter lived together as husband and wife, a judgment of a circuit court in Wisconsin confirming the marriage, in a suit brought therefor by the woman, must be reversed, with instructions to the circuit court to enter judgment declaring the marriage ceremony null and void, one of the findings of that court being that during the period of ten years preceding the trial the man had been subject to occasional attacks of epilepsy, which epileptic condition was caused by the excessive use of alcohol. The court says that the marriage in Minnesota was solemnized contrary to the express prohibition of the statutes of that state and contrary to its public policy. It was solemnized there after a fraud on the clerk of the district court, in his duty to ascertain and to be satisfied that there was no legal impediment to such marriage, had been perpetrated, either by the concealment by or false statement of the man as to his condition on a material and statutory requirement. It could not properly be held that the public policy of Minnesota, in prohibiting an epileptic from contracting a lawful marriage, was contrary or repugnant to the then public policy of the state of Wisconsin, inasmuch as this state then prohibited the marriage of insane persons and idiots; for, although there is a distinction both in the legal and medical sciences between epilepsy and insanity, yet the court may properly take judicial notice that epilepsy is a serious mental disease, and tends to weaken the power of the afflicted person and to injure his posterity. This court would be loath to declare, if not indeed prevented from declaring, that such a prohibition by Minnesota was contrary to the public policy of Wisconsin, in view of the fact that by Chapter 218, Laws of 1917, the legislature amended Section 2330 of the Wisconsin Statutes by inserting the word "epileptic" between the words "person" and "or," where the provision was made that "no insane person or idiot shall be capable of contracting marriage." The marriage ceremony, therefore, which the plaintiff asked the courts of Wisconsin to confirm in this action, was, where performed, contrary to public policy of the state resorted to by the plaintiff for the sole purpose of performing the ceremony, and this court will give it no higher value in Wisconsin than it had there. The mere fact that the unfortunate man, when examined as a witness in the court below, expressed himself as opposed to the action taken by his guardian in asking that the complaint be dismissed and the alleged marriage be declared void, and indicated his desire of having the marriage ceremony confirmed, and the relationship continued, did not alter the situation nor change the duty of the court in disposing of the case. The state has the right to control and regulate by reasonable laws the marriage relationship of its citizens, and the wishes and desires or even immediate welfare of the individual must yield to that of the public welfare as determined by the public policy of the state.

Insufficient Information Against Physician for Prescribing Liquor

(State v. Bradford (Mo.), 201 S. W. R. 913)

The Kansas City (Mo.) Court of Appeals, reversing a judgment of the circuit court, says that this was a prosecution, by information, of a physician for violation of the statute forbidding the issuance of a prescription for intoxicating liquor for other than medicinal purposes. But the information was not in the language of the statute and did not charge the physician with issuing the prescription for the purpose of enabling the liquor to be used otherwise than for medicinal purposes. In other words, the information did not connect the issuance of the prescription with the purpose of the use of the liquor. It was therefore insufficient.

INDIANA STATE MEDICAL ASSOCIATION

Annual Meeting, held at Indianapolis, Sept. 26-28, 1918

The President, Dr. J. Rilus Eastman, in the Chair

Anorectal Fistula

Dr. C. F. Fleming, Elkhart: A careful and free opening of ischiorectal abscesses will prevent many fistulas. It is well to cut as few fibers of the external sphincter as possible. The cut should be a single transverse cut and not a dissection destroying the muscle substance. The most important part of the diagnosis is the demonstration of the internal opening. Those fistulas with a straight tract do well when simply incised and allowed to heal, and burrowing fistulas are best dissected out by some method that avoids destruction of sphincter muscles.

DISCUSSION

Dr. C. C. Terry, South Bend: Our poor results in this line of work are due to incorrect diagnosis rather than to poor technic. Our examinations must be more thorough if we are to have better results; and following thorough examination the important thing is early operation. Often a simple incision, under a local anesthetic, with a small drain, will give relief. When patients are operated on early, forty-eight hours of drainage is all that is necessary.

Study of the Anus, Rectum and Sigmoid

Dr. H. H. Wheeler, Indianapolis: The anorectal line has a very important clinical significance in that it is the point at which the blood supply is differentiated. Above this line the blood is supplied by the superior hemorrhoidal artery, a branch of the inferior mesenteric, and returned through the portal circulation; below this line the blood supply is taken care of through the systemic circulation and returned through the inferior vena cava. The anorectal line also differentiates the lymphatic current and the nerve supply. The rectosigmoidal junction is the point of retention of effete matter, and also the most frequent site of malignancy. Spastic constipation occurs very often from a lower bowel disturbance that hinders the complete evacuation of the bowel.

DISCUSSION

Dr. W. H. Foreman, Indianapolis: The anorectal line is most important in cases of constipation, because until the fecal matter has passed this line the entire act of defecation is beyond control. Beyond the anorectal line it becomes a conscious matter, a matter that we can to a certain degree help or retard—and here is the cause of so many cases of constipation, because instead of making an effort to expel the fecal contents, the activity is inhibited and the fecal contents remain in the rectum and, therefore, below the sympathetic rectal reflexes—the conscious rectal reflexes. Ninety-five per cent. of all constipation is spastic and is due to an accumulation of material in the sigmoid that Nature is unable to expel.

Syphilis as It Pertains to the Eye

Dr. Albert E. Bulson, Jr., Fort Wayne: A syphilitic basis for the ocular lesion is diagnosed not only by certain features of the lesion itself, but also by the presence of these lesions in other parts of the body, by physical characteristics, and by the results of the Wassermann test. However, one must not be led astray by a negative Wassermann.

In acquired syphilis, and especially in the early stages, arsphenamin and neo-arsphenamin have proved of value; but repeated administration of the remedy is usually required, and the treatment should be supplemented by mercurial treatment. The iodids are reserved for lesions accompanied by an abundance of exudate. Syphilitic eye affections demand heroic treatment. Therefore, mercurials should be crowded just short of physiologic effects, and if potassium iodid is indicated at all it should be given in large doses. There are, however, no eye affections that yield any better results from prompt and energetic treatment than those of syphilitic origin, though, on the other hand, no lesions are more disastrous if not diagnosed early, and promptly and vigorously treated.

Factors of Safety in Hysterectomy

Dr. Donald Guthrie, Sayre, Pa.: The three most important factors of safety in this operation are: First, the preparation of the patient. I do not give any preoperative purge, believing it to be a harmful measure. Large amounts of fluid are lost in the purge, and a night that should have been spent in comfort and rest is a veritable nightmare. In case of nervous, excitable patients, or those suffering with insomnia, I advise a few days' rest in the hospital prior to operation. Second, the position of the patient during anesthesia. I advocate the Trendelenburg position when the patient is put to sleep. This means less handling of the intestine and consequently less trauma. Third, postoperative care. The patient should be made as comfortable as possible. Food is given early because it is the best stimulant for peristalsis. A catheter is used only when all other methods fail. I have had no postoperative hemorrhages. In 551 hysterectomies the mortality rate was 1.2 per cent.

Industrial Clinics and Welfare Work as an Industrial Asset

Dr. M. A. Austin, Anderson: As the necessity for making physical examination of employees has been shown to be desirable, the industrial clinic has been established. The average physician would be much surprised to visit some industrial plants and see the equipment provided for the welfare of employees. At one place in Chicago I found a hospital furnished with twenty beds, a surgery completely equipped for any kind of operation, a staff of seven doctors and twelve nurses, a laboratory equipped for roentgenographic work, and an expert in charge of the chemical and microscopic department, doing everything in the way of bacteriologic and serologic work. A Wassermann test was made in every fracture case and in every case in which there was delayed healing in a wound. In a conference with the heads of departments I asked as to the benefits, not only to the company but also to the employees, and they stated that it was the best investment the company had ever made. In former years many unjust claims were paid, which is largely obviated by this supervision of employees. This company, in common with many others all over the country, requires a physical examination of each employee, not only as a safety first measure, but also that each employee may be given the kind of work for which he is best fitted physically.

Infant Conservation

Dr. Ada E. Schweitzer, Indianapolis: The multiplicity of agencies already at work indicates general interest. There is need, however, for organization and centralization of efforts. Effective infant conservation will depend primarily on the care the infant receives, and includes considerations of heredity, prenatal care, care at birth, and all conditions affecting postnatal and infant care. As means of securing proper care we suggest: (*a*) Special education and training of physicians, nurses, teachers, parents and children, each concerning the phase of the work in which he may best aid. (*b*) The provision of adequate service, medical, nursing and hospital facilities available to all. The administration of this division of public health work by special departments established in state boards of health. A nation-wide adaptation of the statistics and suggestions furnished by our national clearing house, the Children's Bureau, U. S. Department of Labor, in the formulation of plans for this work; that the most practical and efficient organization may be accomplished with the least waste of money, energy and time.

Prenatal Care

DR. C. O. McCORMICK, Indianapolis: Prenatal care is conserving the health and strength of the prospective mother; it is foresight and forehandedness during pregnancy; it is preventive medicine applied to obstetrics; it is an effort to prevent mistakes and mishaps to both mother and infant before and during childbirth; it is an effort to give mother and infant the greatest possible chance. The chief results of this work are that it lowers the infant death rate under one year; produces healthier babies; reduces the number of stillbirths and miscarriages; increases the number of normal births; reduces the number of toxemia and eclampsia cases; increases cases of maternal nursing; reduces maternal mortality; helps eliminate the midwife, and last, but not least, elevates the standard of obstetrics, making it a line of work attractive to the young physician.

DISCUSSION

DR. JANE KETCHAM, Indianapolis: We began last May to examine the children, and in this work we had the cooperation of the medical school, of the physicians, and also of the hospitals and the Public Health Nursing Association. We had in all 212 clinics in which 17,000 children were enrolled. Some were not examined, but many were. In the country districts the greatest cooperation was seen, the people being much interested. In the city we sometimes had no children at all, and at other times the clinics were overflowing. We are already seeing the benefit of the follow-up work. Children are being brought to the medical school clinics and to private offices to see if the defects that we pointed out can be remedied. I feel that this work has been of great advantage to the community, and it certainly is a stimulating field in which to work.

DR. LOUIS ROSS, Richmond: In Wayne County about half the children were registered, and we examined about half of those, so that we examined one fourth of the children under 6 years of age. We are undertaking follow-up work through our social service bureau and a group of volunteer visitors, and the results are very encouraging.

DR. W. A. FANKBONER, Marion: The success of this movement does not depend entirely on the physician. It depends on organization and publicity. If you give the American community a vision of the importance of this work, the people will come to the standard.

DR. N. BAINBRIDGE POWELL, Marion: This campaign for child welfare was very well carried out in our county, but the important thing now is the follow-up work. Our mothers are interested and are willing to do what they are told; but the agencies back of them—the grandmothers and all the talk that is brought to the home—is what we have to fight.

Clinical Significance of Blood in the Urine

DR. H. O. MERTZ, Laporte: Any urinary hemorrhage is an expression of a pathologic lesion along the urinary tract. No definite conclusion can be formed by simply studying the symptoms of hemorrhage, as a malignant process may cause so little bleeding that no anxiety is aroused in the mind of the patient. The most confusing and difficult case of urinary hemorrhage I have seen was due to a small papilloma of the urethra that I had repeatedly overlooked in my examinations. This growth was near the external urethral meatus, and at times a drop of bright red blood would pass from the resting urethra. At urination the first urine contained much blood, while the last showed only microscopic blood.

DISCUSSION

DR. M. JOSEPH BARRY, Indianapolis: The diagnosis of blood in the urine is easy, a microscopic examination of a fresh specimen of urine being all that is necessary; but once the condition has been diagnosed, it becomes of the utmost importance to determine the origin and cause, and this may be done in a majority of cases if we take advantage of the modern methods of diagnosis. After exhausting all of these methods with negative results, there is, however, a certain residue of cases that formerly were designated as "essential renal hematuria," "angioneurotic renal hematuria," "renal epistaxis" and "renal hemophilia." We are not justified in saying there is no lesion back of the hemorrhage because we cannot find it. The most careful observers who have studied the postoperative and postmortem material in these cases have been able to demonstrate evidence of minute foci of infection in the kidney substance; so we must not close our eyes to the possible gravity of the situation in any case in which blood appears in the urine.

DR. BERNHARD ERDMAN, Indianapolis: In the larger cities the commonest cause of gross as well as microscopic evidence of blood in the urine is gonorrheal infection.

DR. L. F. SCHMAUSS, Alexandria: We should not wait for blood in the urine to diagnose renal disease.

Infection and Toxemia in Relation to Glandular Organs

DR. HUGO PANTZER, Indianapolis: Removal of the focus or foci of infection wherever located in the entire body, removal of anatomic irregularities, and active eliminative treatment, medicinal, hydrotherapeutic and hygienic, will restore most cases to normal. The resort to organ therapy fails in many cases unless accompanied by active eliminating measures. Associated, the two do well in those cases in which, under like conditions of disease of the organs of digestion, we administer pepsin, trypsin, pancreatin, etc. In the many cases in which my efforts were limited to the surgical and eliminating measures mentioned, my experience was such that the organ products, as now understood and applied, are of little avail. However, relief from them comes most happily in those cases in which the effects of toxemia and bacteremia have routed all physiologic function for the time or permanently.

Cesarean Section and Obstetric Operations Under Nitrous Oxid-Oxygen Anesthesia

DR. I. McKESSON, Toledo, Ohio: If there is an ideal anesthetic for obstetric operations, it is nitrous oxid. Its transient effect when removed permits almost immediate resumption of normal labor; its lack of depression on uterine and other muscles when properly administered, its safety to mother and child, and the means at hand for perfusing the child with oxygen through the mother while the cord pulsates, are factors that should decrease fetal and maternal mortality and morbidity in operative obstetrics. The hope of reduction of morbidity and mortality in general rests in great measure on the disposition of the midwife, who delivers 50 per cent. of the parturients in the larger cities.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

Sixty-Eighth Annual Session, held at Philadelphia, Sept. 23-26, 1918

(Concluded from page 1771)

Intraspinal Auto-Aminized Serum Treatment of Cerebrospinal Syphilis

DR. B. A. THOMAS, Philadelphia: Arsphenamin therapy, either intravenously or intraspinally, cannot restore degenerated spinal cords. Intraspinal treatment accelerates the restoration of the spinal fluid to normal, arrests the degenerative process and insures greater permanency of therapeutic results. Intraspinal treatment by auto-arsphenaminized or arsphenaminized auto-arsphenaminized serum injections should supplement intensive intravenous therapy when necessary. Cases of endarteritis with vascular or circulatory disturbances and those with exudative gummatous meningitis, also many cases of tabes dorsalis, respond satisfactorily to intravenous therapy alone. Cases with marked tract or cortical degeneration offer little, if any, hope of improvement. Treatment in qualified cases should be continued until the findings in the spinal fluid, as well as the blood, are rendered negative, except globulins, which may persist positive in many cases irrespective of the amount of treatment. Mercury and the iodids continue to be indispensable supplementary therapeutic aids in the treatment of cerebrospinal syphilis.

DISCUSSION

DR. LORAINE L. SCHWARTS, Pittsburgh: Unless the general medical profession universally recognizes the necessity for routine lumbar puncture in all cases of syphilis I believe we shall have in twenty years as many posterior sclerosis tabetics, paretics and cerebrospinal cases as we are having under the old treatment. Opportunities for better work in this field rests primarily with the physician having charge of the patient during the first six months of his infection. I do not in all cases delay exploration of the spinal canal until I am ready to discharge the case. If there is the slightest sign of central nervous involvement, resistance to therapy, or persistence of strong Wassermann within the first three months I have the spinal canal explored and in many of these cases I think we save the patients many intravenous doses of arsphenamin by starting the spinal treatment early. I am particularly in accord with the skeptical views held by many neurologists regarding the effect of treatment because when the patient reaches the neurologist the anatomic changes present render the case unpromising.

Dr. Jay F. Schamberg, Philadelphia: I am in full accord with the deductions drawn by Dr. Thomas on the intraspinal treatment of cerebrospinal syphilis. It is impossible to cure cases of parenchymatous diseases of the nervous system if degenerative changes have already taken place. The colloidal gold test warns us in advance of impending changes in the nervous system. It is essential that we examine the spinal fluid in all patients in whom a negative blood Wassermann is obtained. The time to cure paresis is before clinical evidences of the disease develop.

Dr. Alfred Gordon, Philadelphia: I have had an experience of several hundred cases of neurosyphilis, and in some brilliant results have attended the first or second administration of autoneo-arsphenaminized serum. I have also had some very regrettable results. Generally speaking, I find no parallelism between laboratory findings and clinical symptoms. While the old methods of treatment of neurosyphilis are good, the intraspinal method is an excellent adjunct.

Dr. Paul G. Weston, Warren: In our hospital we divided our paretics into so many groups giving each a different treatment; one group was given no antisyphilitic treatment. We found practically no difference in the average length of life of the treated and the untreated patients. At necropsy the same changes were found in the brains of the treated and untreated.

Application of the Principles of Advanced Psychiatry

Dr. J. Allen Jackson, Philadelphia: The principles are expressed in the functions of mental hygiene, and combine the knowledge gained in custodial institutions with community forces. They are applicable to rural communities, municipalities, or states. In communities with a population over 500,000, community service would best be obtained through a municipal bureau of mental hygiene. To secure cooperation with outside organizations such a bureau should be under the supervision of a trained psychiatrist with subordinate district supervision. In such districts there would be designated definite psychiatric centers under the direction of an alienist assisted by a trained field worker. At these centers public education could be encouraged, early care and treatment with definite assignment to proper institutions, custodial psychopathic, preventoriums, or general hospitals, could be made. The alienist in charge of the psychiatric center would bear the same relation to the custodial institution as the medical inspector of the bureau of health bears to the hospital for contagious diseases. The chief officer of such a bureau should be a conservatively progressive psychiatrist experienced in intramural and extramural psychiatry. The alienist assigned to each center should be a practical man of broad experience and training. The field workers should be graduate nurses with general hospital and psychiatric training and a keen insight of human nature. The immediate effect of such a bureau would be a temporary increase of custodial patients, counterbalanced, however, by the probability of an increased recovery rate. The effect on the indigent and permanently insane would be speculative. Early diagnosis and appropriate treatment would be assured. The interest of patients and their relatives would be safeguarded. The propagation of the mentally unfit would be checked, and the cost to the municipality and state of the care of these unfortunates would be eliminated.

DISCUSSION

Dr. John A. Lichty, Pittsburgh: I am in accord with Dr. Jackson's method of organization. Work of this kind means economy and efficiency, the saving of lives and bringing back to health many people now submerged.

Dr. S. Solis Cohen, Philadelphia: I wish the same plan might be inaugurated in our dealing with tuberculosis. By our defective hygienic organizations we produce a large number of tuberculosis and insanity cases. Having produced them, we save a few in a half-hearted fashion and then allow them to lapse.

Dr. E. E. Mayer, Pittsburgh: Unless physicians get away from the individualistic, they will loose their prerogative of the confidence of the community; social and vocational workers will take up the spheres of activity which should be, in part, those of the medical profession. Hygiene should deal with the social problem of the community as well as the mental. Until we have a plan by which these various agencies work with the medical profession I fear we shall accomplish but little. I trust that our state authorities and organizations may attack the problem from this standpoint.

Prof. Norbert J. Melville, Philadelphia: The Mental Hygiene Committee of the Public Charities Association is prepared to cooperate with physicians in any community who are ready to direct that type of cooperation. We are already working through welfare agencies to convince social workers that they ought to go to the specialist for direction in social psychiatry and that the social agencies ought to send some of their staff for a time to take a course in the principles of social psychiatry. It is the thought of the committee that with the organization of volunteer workers eventually the state may take over the work.

Serum Treatment of Epidemic Cerebrospinal Meningitis

Dr. John A. Kolmer, Philadelphia: The serum treatment of epidemic cerebrospinal meningitis by the intraspinal route of injection has reduced the gross mortality of 70 to 90 per cent. among patients not treated with serum to 30 per cent. or less. The problem is complicated because more than one type of meningococcus is capable of producing the disease, and by the fact that the micro-organism may be carried and disseminated by convalescents and by healthy carriers. It is highly important to employ a potent polyvalent serum in the treatment of meningococcus infections because at the present time type diagnoses and the employment of monovalent serums in treatment are not yet available as in the diagnosis and treatment of lobar pneumonia. Investigations in the Army and Navy have shown that the majority of cases of meningitis are due to previous contact with a patient or a healthy carrier of the coccus. During epidemics of the disease between 1 and 2 per cent. of persons are chronic carriers and these constitute the greatest source of danger. Treatment and management of the chronic carriers are as puzzling as of the healthy carriers of virulent diphtheria bacilli. The successful treatment of meningococcus meningitis with serum depends largely on early diagnosis and the proper administration of sufficient serum of high potency and polyvalency. With the least clinical suspicion of meningitis the physician should resort to spinal puncture without delay. The micro-organisms are regarded by Flexner as infecting the meninges by direct extension along the lymphatics of the olfactory nerves with their occasional presence in the blood stream; recent studies, particularly of Herrick and Baeslack indicate that the coccus may be present in the blood more frequently than heretofore thought and that this "meningococcus sepsis" may produce systemic symptoms. It is my custom to culture the blood routinely at the time of spinal puncture. If after two intraspinal injections of large doses of antiserum improvement is not shown clinically and in the analysis of the cerebrospinal fluid, I advise that the serum of a second manufacturer be substituted, hoping that the second serum may contain specific antibodies for the particular type of meningococcus producing the disease which were absent from the first serum. Our main interest in the serum therapy of meningitis has been concerned with the influence of fresh normal serum alone and in combination with antimeningitis serum on virulent meningococci. On the basis of our experimental results we believe it is logical to complement the antimeningitis serum before intraspinal injection by the addition of at least one cubic centimeter of fresh human or guinea-pig serum to each 9 c.c. of antiserum, particularly in the treatment of serum-resistant cases. We have not yet been able to give this method clinical trial. It seems worthy of use in further efforts toward improving the results of the serum treatment of meningococcus-meningitis.

4. **Transportation of Wounded.**—Allison calls attention to the fact that an equipment of splints and surgical dressings and appliances has been described in a small volume called a "Manual of Splints and Appliances for the Medical Department, U. S. Army," issued to the Army under Special Order 73, Paragraph 17, and approved by the Commanding General of the Expeditionary Force. This volume has been distributed to the medical officers of the division in the field and to those in all hospitals in the Zone of Advance. The splints therein described have been demonstrated to all battalion and regimental surgeons, and to the commanders of all the ambulance companies and the enlisted personnel of the same. Practical drills have been held, and competition started to develop efficient, rapid and proper application of these splints, so that in the divisions already actively engaged a practical knowledge exists of the value of traction and fixation in the support of fractured bones and injured joints. The type of splints selected by the Splint Board has, so far as experience goes, met existing conditions in a most satisfactory manner; the splints are easily applied and give, in a simple and readily understood manner, the exact principles of treatment insisted on by the Division of Orthopedic Surgery.

5. **Hemorrhagic Osteomyelitis and Sarcoma in Bone.**—In this paper the attempt is made to differentiate the lesion termed "hemorrhagic osteomyelitis" from the true sarcoma found in bone, and to demonstrate that to group this affection with the malignant bone neoplasms is not justified. Barrie is of the belief that a diagnosis of malignancy cannot and should not be made or based on the giant-cell content in such processes. A correct and confirmatory diagnosis rests on the variety and architectural arrangement of the other cells occupying the microscopic field. It is absolutely essential to recognize that giant cells, of the type commonly found in some of the low-grade malignant sarcomas, are also present in most of the noninfective low-grade inflammatory processes in bone, wherever destruction has occurred and regenerative and reconstructive effort is taking place; the latter being evidenced by the presence of vascular granulation tissue filling up destroyed areas or cavities. In true sarcoma, regardless of the degree of malignancy, there is never a resting stage; the increase in size of the neoplasm is progressive and constant. No apparent effort at regeneration or reconstruction of normal tissue occurs. In hemorrhagic osteomyelitis, increased bone destruction, following initial injury, is due to nutritional inhibition and necrosis of bony structure resulting from pressure of the proliferative granulation tissues. Hand in hand with destruction, efforts at regeneration and rebuilding of normal structure go on, evidence of which is seen in the formation of primary elemental granulation tissue. Eight cases are cited.

7. **Symptoms Attributed to Lesions of Sacro-Iliac Joint.**—A thorough anatomic and clinical study of lesions of the sacro-iliac joint and of analogous conditions seen so frequently following injuries to joints elsewhere in the body leads Cofield to the belief that the lesions are none other than acute and chronic sprains of the sacro-iliac joint. The pain is doubtless due to the stretching or tearing of some of the fibers of the posterior ligament at the time of the injury, and it may continue for an indefinite time if efficient immobilization of the joint is neglected. The pain in the lumbo-sacral region and buttocks is to be explained by the excessively prolonged effort of the posterior musculature in guarding against joint movement, just as any other continued muscular action, unduly prolonged, will result in a severe aching pain. The sciatic pain is explained by the mechanical irritation of the nerve as it passes through the groove formed by the outer and inner hamstring muscles. These muscles being in a state of spasmodic contraction produce an irritation of the nerve, which causes pain which is referred to the distribution of its branches below the lesion. Further evidence which confirms this theory is furnished by the fact that these patients will almost invariably state that the sciatica appeared immediately following the manipulation. Cofield says that careful study of the anatomy and functions of the sacro-iliac joints precludes the possibility of subluxation or relaxation occurring, except in severe crushing injuries or possibly during the later stages of pregnancy, when all pelvic ligaments are in a state of temporary relaxation. The remarkable results achieved by bonesetters and osteopaths in the so-called "luxations" and "misplacements" of the lower spine or sacro-iliac joint may be attributed to their manipulation of the joint and massage of the muscles, which may modify or relieve the symptoms after one or many treatments, depending on how soon they give the patient the "proper twist."

28 Story of Evian les Bains. R. B. Mixsell.—p. 541.

23. **Treatment of Diphtheria.**—Hoyne is convinced that far too much whisky is used in the treatment of diphtheria. Strychnin, he says, should only be given for a brief period to tide over some emergency. The indiscriminate giving of strychnin from the time a diagnosis of diphtheria is made until the disease has run its course is extremely likely to produce dire results. The chief requisite of the heart in diphtheria is rest. If stimulants must be given over a prolonged period, some form of digitalis, in Hoyne's experience, has usually produced the best results. The chief value of strychnin is as an emergency measure in case of collapse.

As to the dosage of antitoxin, while each case must be judged on its individual characteristics in arriving at the proper dosage, in Hoyne's experience the following scale has served as a fair guide: 1. Purely tonsillar cases, from 5,000 units to 10,000 units. 2. Laryngeal, 10,000 units to 15,000 units. 3. Pharyngeal (including tonsils), 15,000 units to 25,000 units. 4. Nasal or nasopharyngeal, 20,000 units to 50,000 units. The doses will vary somewhat according to the duration of the disease, and the possibility of more than a single type occurring in the same patient must not be overlooked. If possible, the maximum amount of antitoxin required for a given case should be administered as soon as determined. Nothing is to be gained by a division of the dose, that is, by repeated small doses. Hoyne favors the intramuscular injection into the outer side of the thigh.

24. **Hemoptysis Following Exploratory Puncture of Chest.**—Caillé urges that the clinician bear in mind that in acute cases in which a puncture seems indicated, the introduction of an exploratory needle into a thorax containing a highly congested lung is attended with some degree of risk when cyanosis, and other characteristic signs, point to cardiac or circulatory failure. In obscure, subacute and chronic conditions a roentgen-ray investigation should be made; it may obviate the necessity of a puncture. When exploratory puncture of the chest is performed for the purpose of eliciting the nature of an exudate or transudate, which otherwise reveals its presence by characteristic physical signs, including a bulging of an intercostal space during inspiration, the danger of an internal hemorrhage is practically nil.

25. **Hemoptysis in Children.**—In the five cases cited by Pierson, the hemoptysis was due to bronchial gland tuberculosis, pressure on, and erosion of, a vessel near the hilus by an enlarged gland.

44. **Differentiation Between B. Pertussis and B. Bronchisepticus.**—The value of the complement fixation tests in differentiating between these two organisms was made the subject of a study by Ferry and Klix. In a large majority of the tests, the *B. bronchisepticus* immune serum bound the complement in the presence of both the bronchisepticus and pertussis antigens, while the *B. pertussis* immune serum bound the complement in the presence of the homologous antigen and also the human and monkey strains of *B. bronchisepticus*. It did not bind the complement in the presence of a dog strain of *B. bronchisepticus*.

46. **Elimination of Spurious Presumptive Tests for B. Coli in Water by Use of Gentian Violet.**—Hall and Ellefson describe a method to prevent gas formation by anaerobic organisms, so that a greater proportion of positive tests is referable to coliform bacilli alone. This they propose to accomplish through selective inhibition by gentian violet. The gram-positive sporulating aerobes, among which occasional forms capable of giving positive presumptive tests occur, are also inhibited.

47. **Use of Gentian Violet in Presumptive Tests for B. Coli in Milk.**—While Hall and Ellefson do not feel justified as yet in claiming that the addition of gentian violet to lactose broth leads to the detection of *B. coli* in every case in which gas is formed, yet its use certainly does not interfere with the demonstration of *B. coli*; indeed, it distinctly favors such demonstration. Further, the use of 1 to 100,000 gentian violet in the litmus lactose agar plate does not interfere with the growth or acid producing properties of the organism; rather it eliminates to a large degree the masking of acid produced by *B. coli*, through the inhibition of alkali forming, proteolytic, nonlactolytic, gram-positive sporulating bacilli of the hay bacillus group and prevents spreading growths due to these organisms. Moreover, the inhibition of acidifying cocci is of distinct advantage in the search for *B. coli*.

48. **Petroleum-Ether Method for Isolation of B. Typhosus from Feces.**—Kohn and Krumwiede found that the petroleum ether method for the detection of *B. typhosus* has no advantage over direct plating on a medium which restrains the growth of the associated fecal types. With short periods of exposure it may be successful where direct plating on Endo's medium alone fails. There is a strong tendency to reduction of the number of *B. typhosus*, not necessarily associated with a greater reduction of the accompanying fecal bacteria. The danger of infection to those using the method, however, is sufficiently serious to warrant its condemnation, especially as it offers no advantage over direct plating on differential restraining mediums.

49. **Bacterial Nutrition: Utilization of Protein and Nonprotein Nitrogen.**—The author's conclusions, summarized briefly, are: Bacteria are unable to decompose coagulated native protein when there is no other source of available nitrogen in the test medium. Purified proteose also is resistant to direct attack by bacteria. Gelatin-nonliquefying bacteria and some of the liquefiers are feeble in their action on Witte's peptone. The ability of an organism to liquefy gelatin is no sure indication of its proteolytic properties. Gelatin and casein resemble proteose in their resistance to bacterial attack.

50. **Influence of Carbohydrate on Nitrogen Metabolism of Bacteria.**—This investigation has shown conclusively that fermentable sugars, in moderate amounts, do not affect the nitrogen metabolism of bacteria, provided experimental conditions are favorably maintained, or, in other words, under conditions of favorable environment. The common belief in a so-called "sparing action" of sugars in a protein medium is untenable in the light of these experiments. There is a true sparing action, however, in the sense that the nitrogen is utilized merely for growth, and that the sugar furnishes the energy.

53. **Germicidal Action of Freezing Temperatures on Bacteria.**—Extensive experiments were made by Hilliard and Davis to determine the effect of cold on bacteria. He found that intermittent freezing of bacteria exerts a more effective germicidal action than continuous freezing. The reduction is much less in milk and cream than in pure tap water when freezing temperatures are applied, due, no doubt, to physical protection offered to the bacteria by the colloidal and solid matter in suspension. The degree of cold below freezing is not a very important factor in the destruction of bacteria. There is no critical temperature below freezing where the germicidal effect is greatly accelerated. The death rate of *B. coli* is much higher in mediums which are frozen solid than it is in the same mediums not solid and at a slightly lower temperature. It is suggested that crystallization, probably resulting in mechanical crushing, is an important germicidal factor in causing the death of bacteria at zero centigrade and below. The greatest reduction occurs promptly on freezing and refreezing, but is not caused so much by the sudden change in temperature as by this mechanical factor.

59. **New Operation for Hallux Valgus.**—In the operation done by Rugh the joint is exposed by a curved, longitudinal incision and the flap (base down) is dissected free to the lower edge of the joint. A tongue-shaped flap is then made (base backward as in the Mayo operation) and should include the bursa and the internal portion of the capsular ligament back of the base of the proximal phalanx of the great toe. This is turned backward and the lower end of the metatarsal is freed of ligamentous attachments. With a sharp osteotome or chisel, sufficient of the epiphysis of the metatarsal is then removed to allow straightening of the great toe. This usually amounts to about one-fourth inch. This cut also is made slightly diagonal from within outward and from behind forward. The inner sharp and hypertrophied corner is next removed with the osteotome. The top and under parts of the epiphysis are then taken off to make a wedge-shaped end on the bone. The slant on the top can be made very much greater than underneath so as to leave as much weight-bearing surface as possible. There will also remain the supporting surfaces of the sesamoid bones on the under surface of the joint. The tongue-shaped flap is then passed across the end of the bone, covering in the wedge and secured with sutures if necessary. Sutures are then passed from the base of the tongue-shaped flap on the inner side to the base of the proximal phalanx, sewing back and forth to hold the toe toward the inner side. The skin incision is next closed and dressings applied to hold the toe inward. The bandage should make a figure-of-eight about the toe and foot and hold the toe horizontal and slightly adducted. In some cases a splint of wood or plaster may be advisable, but this is seldom necessary. After two weeks' time the use of the foot is permitted and weight bearing advised.

80. **Orthopedic Cases in First Surgical Division, Fordham Hospital.**—Boorstein cites a case of bilateral pathologic dislocation of the hip joint, the patient being 6 years of age. The condition was the result of a septic arthritis, the sequel of an attack of scarlet fever. He also cites two cases of low lumbar backache due to enlarged transverse process of the last lumbar vertebra. The removal of this process relieved the patient completely of the pain. Another case was one of chondroma following trauma. The patient had received an injury to the dorsal surface of the right foot by pressure of a rocking chair. For three and a half years the patient was suffering from pain in the foot. A swelling the size of a hazel nut, over the external cuneiform, was removed. The pathologic diagnosis was chondroma. Patient made a perfect recovery and has never suffered since. Another patient developed a sarcoma of the trochanteric region of the femur following a fall on the hip. Evidence of metastases in the humerus and lungs were present.

84. **Dangers of Chenopodium Treatment of Uncinariasis.**—The extensive use of the oil of chenopodium in the treatment of uncinariasis makes a study of its untoward effect of real importance. Roth details the joint experience of several men in the medical wards of Santo Tomas Hospital, Panama. One hundred and three patients were given the oil. Twenty-nine showed signs of reaction. Dizziness, nausea and vomiting, headache, deafness and general depression were the symptoms observed. Deafness is by far the most disagreeable after-effect of the chenopodium treatment. It occurs in 20 per cent. of all the cases, varied in intensity from very mild to a complete loss of hearing, and lasts anywhere from one week to several months. In four of the cases, some deafness still persists two years after the date of treatment. No such reaction was observed after the administration of thymol in similar doses. Roth advises that the oil should not be administered unless there be ample facilities for studying the cases before and after administration. This should include a careful determination of the percentage of hemoglobin. Chenopodium should not be administered to a patient suffering from a high grade of anemia, nor should the treatment be repeated within ten days.

103. **Rôle of Ascariasis in Gallbladder Disease.**—Aviles cites the case of a woman who for 26 years had been suffering from attacks of colic-like pain over the right upper quadrant of the abdomen, and occasionally she vomited stomach secretion mixed with bile. On some occasions she expelled round worms with the vomiting, and in one instance, the vomiting of an ascaris relieved the pain. A probable diagnosis of cholecystitis with calculi was made. Cholecystotomy was performed. The walls of the bladder were hypertrophied, but no rugosity of the mucosa was evident. Aviles did not find any calculus, but a big *Ascaris lumbricoides* about 8 inches in length, partially obstructing the cystic duct. The operation was completed by draining the gallbladder. The patient made an uneventful recovery and all the symptoms existing previous to the operation disappeared. Antihelminthic remedies were administered during the convalescent period.

Aviles points out that an individual who is seized with hepatic colic-like pain, accompanied with vomiting of *Ascarides lumbricoides*, has the syndrome necessary for suspecting that the case is one of migration of the parasite or parasites into the biliary ducts or gallbladder; and unless the symptoms subside, surgical intervention is indicated. Antihelminthic remedies must be administered as a prophylactic measure in those cases in which a history of ascariasis accompanies disorders of the gastrohepatoduodenal system. In those cases in which surgical intervention has been practiced, antihelminthic remedies must be given to avoid new serious complications.

106. **Localization of Ureteral Stone.**—The method described by Kretschmer was suggested by E. Ball. In a case in which a diagnosis has been made of possible ureteral stone, the shadowgraph catheter is passed in the usual way. A roentgen exposure is taken with the catheter in place. A second exposure is made on the same plate without changing the position of the patient or without changing the position of the plate, but by changing the position of the tube, so that a double exposure on one plate is obtained. This method is not new in radiography, as it has been employed in the localization of foreign bodies in various parts of the body.

107. **Loose Bodies in Abdominal Cavity.**—The loose body which was removed from the region to the right of the midline and anterior to the true pelvis in Emmert's case was almond-shaped, 3 cm. long, 2 cm. in breadth, and 1.5 cm. in thickness. It weighed 50 grains. It was light brown in color and covered with a grayish secretion. There was no evidence of a vestigial pedicle or adhesion. On one side was a calcified plaque occupying about one third of the surface. The consistency was rather firm. The body cut with a grating sensation and revealed a distinct capsule about 1 mm. thick enclosing a finely granular material of a yellowish brown color. Interspersed in this were several small particles of a hard, colorless material. No definite nucleus was seen. The contents of the capsule gave a very strong positive guaiac test for blood. Under the microscope it was seen to be composed of fat droplets, crystals, and blood corpuscles. The capsule was in such a state of disintegration as to prevent a diagnosis of the tissue.

111. **Studies in Paleopathology.**—A considerable number of intensely interesting as well as instructive references are given by Moodie to show that the remains of fossil man and

extinct animals show evidences of diseases which are comparable to recent lesions. Indications of disease are rare compared with the abundance of remains of ancient races. This may indicate that disease was not so prevalent in the past as at present, although it must be remembered that the evidence is all skeletal. Some of the lesions seen on fossil and subfossil remains are: osteoma, hemangioma, fractures, callus, osteoperiostitis, necrosis, caries, alveolar pyorrhea, hyperostoses, osteomalacia, spondylitis deformans. These and many other interesting lesions show that disease is no new thing but has been manifest in a diversity of forms for many millions of years.

114. **Suture of Blood-Vessel Injuries from Projectiles of War.**—According to the statistics gathered from various operators engaged in service in the front area with the British forces, Goodman says all seem agreed that gangrene follows the ligation of the popliteal artery in a very large percentage of cases. When gangrene does not supervene, however, the patient frequently suffers from the concomitant symptoms of an impaired circulation. In the five cases cited, wounds of the vessels (3 popliteal and 2 femoral) repaired by suture showed an early and satisfactory restoration of patency, and gangrene from an insufficient blood supply was thus warded off. Goodman suggests that the failures in many of the cases reported may have been due to neglect of one or more of the essential points of the operation, which are: 1. A high degree of asepsis. 2. The segment of vessel to be sutured must be freed from all macroscopic blood and properly protected from all contact during the suture. 3. The sutures must not be introduced under too great tension. 4. Thrombosis is favored by bacterial infection, and by the tissue juices with their ferments. The lumen of the vessel to be sutured should, therefore, be washed thoroughly with Ringer's or saline solution, followed by liquid paraffin. Sutures introduced under tension may cut out and induce hemorrhage. When a main artery is completely severed, a circular suture should not be attempted unless the severed ends can be approximated without tension. When this is not possible, a segment of vein can be transplanted, or when such a procedure is not practical a paraffined tube may bridge the gap and maintain the blood supply until an enlarged collateral circulation is established. The tube should then be removed.

115. **Safeguard in Inguinal Route Operations for Femoral Hernia.**—When the bowel is strangulated or incarcerated, Ware divides the constriction from within by means of a fine silk thread. This thread can be passed by means of a Deschamp needle or any needle sufficiently blunted, or by means of the eyelet of a fine silver probe. By gently whipsawing the thread, a very exact and partial division of the fibers of Poupart may be executed, which can never injure the intestine, and sometimes the slightest excursion of the thread will be sufficient to reestablish the circulation of the intestinal contents and render the reduction of the intestine possible. The thread may even be used as a tractor during the reduction. Thereafter it is divided and withdrawn.

117. **Relief of Lateral Tension in Cleft-Palate Operation.**—In order to prevent the cutting of the suture through the soft tissue, Federspiel has devised a new tension plate which will prevent the suture from cutting out and at the same time relieves the tension as well as renders the palatal tissues inflexible. These plates are made from noncorrosive metal, B. I. B., American gage 22, in various sizes and types. In order to fit these plates, it is necessary to make a small incision near the gingival border of the last molar, being careful not to cut the palatine artery. The incision should be of sufficient length to permit the flange of the plate to enter and lie between the palatal bone and soft tissue. Previous to fitting these plates it is necessary to pass silver wire (American gage 24) through the mucoperiosteal flaps and then through the holes in the plates. The ends of the wire are then passed through perforated lead shot and made tense by pulling the wire and crushing the shot, after which the borders of the flaps can be approximated without tension. After this is done, Federspiel denudes the border of the cleft and places and ties the coaptating sutures after the McCurdy method.

118. **Placental Tissue as a Galactagogue.**—The value of placental tissue as a galactagogue is endorsed by Cornell. He says that 87 per cent. of the babies whose mothers had received placental tissue began to gain on the fourth and fifth days, against 69 per cent. whose mothers did not receive the medication. Forty-four per cent. regained their birth weight before leaving the hospital against 24 plus per cent.

1. **Treatment of Gas Gangrene by Mixed Serums.**—Convinced by previous experience of the curative value of the antiperfringens serum prepared by Weinberg and Sequin at the Pasteur Institute, Ivens tested the preventive use of antigangrenous serum. From March 21 to September 6, 1918, 3,660 recently wounded received their first operative treatment in the hospitals under his care, and the results obtained are set forth in this paper. Ivens has employed in three series of cases: (a) the mixed serums antiperfringens, antivibrion septique, anti-oedematiens, prepared by Weinberg and Seguin. (b) the polyvalent serum of Leclainche and Vallee. (c) a combination of the two.

Antigangrenous serums were given preventively in 433 cases, all of a severe type, including nearly 300 fractures, many cases already presenting one or other of the clinical signs of gas gangrene, such as crepitation, discoloration of muscle, bronzing of skin, edema, and bad odor. A large number were cases of wounds of the lower limbs. Nearly all patients were received within the first twenty-four hours after being wounded. The serum, given subcutaneously in dilution, Ivens believes has averted the anaphylactic phenomena which have been observed in cases in which this method of procedure has not been followed. When the mixed serum was given at or before the first operation (222 cases), no patient died from gas gangrene, although there were nineteen deaths out of the number from the effects of shock, from multiple fractures, hemorrhage, meningitis, or streptococcal septicemia. In fourteen of these cases the serum was administered at the same time that amputation was performed for massive gas gangrene. Of these fourteen patients, twelve recovered. The two fatalities occurred at the end of a fortnight from streptococcal septicemia, all signs of gas gangrene having disappeared for more than a week. In a very large number of cases the administration of mixed serums has permitted conservative treatment to be adopted instead of the amputation which would otherwise have been inevitable.

The value of this serum as a disintoxicating agent has been proved in several cases. Its administration has made it possible to wait for some hours until the condition of the patient has improved sufficiently to allow of surgical measures being employed. Infected cases, where mixed serum was omitted either by accident or from the meager supply, have not done as well as other cases in which the patients made a good recovery.

Polyvalent serum was used in 154 cases, nineteen were fatal, six of the deaths being due to gas gangrene; three had also a concurrent streptococcal septicemia. In fifteen of the 154 cases amputation was performed for massive gas gangrene, with eleven recoveries and four fatal results. Of these fatal cases, two were also associated with streptococcal septicemia. It was generally noticed during the period in which the polyvalent serum was given preventively that, except in gas gangrene, the cases seemed to run a straightforward course, without severe streptococcal infections, and that secondary operations on this score were infrequent. Among fifteen cases of streptococcal septicemia, only four had received preventive doses of this serum. Seven patients who had all been treated with fairly large doses of polyvalent serum recovered.

In a third series of cases (fifty-seven) 10 c.c. of polyvalent serum were added to the initial dose of 30 c.c. of mixed serum. Although in ten of these cases gangrene was already present in the form of cellulitis or abscess, in only one did massive gas gangrene develop, namely, after ligature of the external iliac artery, fifteen days after the preventive dose of mixed serum had been given. Two cases were fatal in this series. Although many of these patients had badly infected fractures of the lower limb, only three sustained amputations, one for streptococcal infection, two for secondary hemorrhage. Not only has it been possible in these cases to adopt conservative lines in fractures of the diaphysis, but, in addition, wounds involving the articulations—hip, knee, shoulder, ankle and tarsus—have run an unusually favorable course. In secondary operations, where latent microbes in sequestra so often cause a disappointing result (secondary suture, reamputation, etc.), a preventive dose of polyvalent serum and mixed serum has been found useful.

16. **Case of Absence of All Sensation.**—Roberts cites the case of a soldier, aged 37, far removed from the neurotic or hysterical type, whose family and personal history is negative, except for an attack of yellow fever at the age of 17. Since then he has noted absence of all sensation. There is complete absence of both superficial and deep tactile sense over the whole skin surface, and also over mucous membrane, where attainable. There is no consciousness of deep vibration. He does not feel the ground with his feet, and experiences difficulty when walking at night. He says that his inability to bring his heels together at the command "Attention" without controlling the movement with his eyes has frequently led him into trouble with his drill sergeant. There is complete inability to recognize objects placed in the hand when the eyes are shut. Sense of pain is completely absent. He underwent the radical cure of double inguinal hernia without anesthetic of any kind, being totally unconscious of any sensation either of pain or touch. He never suffers from headache, toothache, abdominal or other visceral pain of any description. The cornea shares in the general anesthesia. Thermal sensation is also absent. There is no perception of temperature in food or drink. There is insensibility to atmospheric changes of temperature.

The muscular sense appears to be completely absent. With the eyes closed, if asked to make any movement with his arms—the choice of movement being left to him—he is incapable of doing so, saying he cannot tell if his arms are moving or not, and all he can accomplish is a slight convulsive twitching of the hands and arms. On the other hand, if, when standing upright, with closed eyes, he be told to walk toward the observer he does so without trouble. He is a good swimmer. The sense of position is absent. He exhibits the phenomenon of the fixation of the limbs in the positions in which they are placed. Sense of taste is completely absent. The sense of smell is practically nonexistent. The fumes of the strong solution of ammonia and of pure hydrochloric acid produce a faint sensation of an odor which the patient remembered to have smelt in his youth.

The only response on both sides to plantar irritation is slight abduction of the little toe. The patellar reflexes were present and normal. The orbicularis palpebrarum muscles contracted on touching the cornea, though no sensation was evoked. The pupils reacted to light and accommodation. The bowels usually act regularly once a day. There is no conscious desire to defecate beyond what he describes as an occasional "rolling" in the abdomen. He never makes any effort, nor is there knowledge of the passage of the feces. Only when there is looseness of the bowels is there any incontinence. Micturition ordinarily occurs during action of the bowels once in twenty-four hours at about 8 o'clock in the morning. There is never a desire to micturate.

Finally, he seems to be without most of the common emotions. He is without family affection. He makes neither friends nor enemies. He has no love of country or home, but he is a smart and efficient soldier and takes a pride in it. The diagnosis of syringomyelia combined with hysteria is suggested as one which seems to meet the case.

19. **What War Has Taught Us About Tetanus.**—Bazy says that the war has shown that: 1. Antitetanic preventive serotherapy is efficacious in the immense majority of cases. 2. When it acts incompletely it so modifies the course of tetanus that it has created new forms of the disease, unknown before its use was general. 3. The study of the check to serotherapy ought to lead (*a*) to use the serum in a more rational way; and (*b*) to know how to complete its action by that of an antitetanic vaccination. The pathogenic medication is the injection of antitetanic serum. The intracerebral route, supported by Roux and Borrel, has been almost abandoned. The intrarachidian route seems of little practical use. Of all the methods it seems that one alone may be

sufficient and free from all criticism: that is the subcutaneous method. But, pathogenic medication, powerful though it is, has need of being completed by symptomatic medication, which is directed to the nervous phenomena. The alkaline persulphates possess in the highest degree the power of destroying the tetanic poisons. A solution of procain, 1.5 per cent., with the addition of a drop of epinephrin, 1:1,000, injected at the level of the brachial plexus for the upper limb, at the point of emergence of the sciatic for the lower limb, and in the vicinity of the nerve trunks controlling the groups of the contractured muscles, has given in all cases most encouraging results.

Bazy has employed as vaccine an iodized toxin, the same as is used at the Institut Pasteur to prepare the horses providing serum. The power of the toxin is such that 1/10,000 c.c. sufficed to kill a guinea-pig of 400 grams. On mixing this toxin with an iodized solution (iodin 1 gm., iodid of potassium 2 gm., distilled water 200 gm.), in the proportion of two thirds of toxin to one third of iodized solution, there is obtained a liquid neutral for the organism, but yet capable of vaccinating it. There can easily be injected the first time 4 c.c. of iodized toxin, the second time 8 c.c., and the third time 12 c.c. It is possible to increase further the number and dose of the vaccinal injections, which are remarkably well borne and provoke neither local nor general phenomena.

20. **Tetanus Consecutive to Superficial Wounds and to Trench Foot.**—Raymond cites two cases of tetanus consecutive to a very superficial wound, so superficial that the wounded man did not present himself for treatment, and consequently did not receive preventive injection of antitetanic serum. The treatment was based on: 1. Excision of the wound. This was carried out as in the case of a malignant tumor, by circumscribing very widely the whole region of the wound. The object was to remove the tetanigenic germs with the tissues which contained them, without causing the penetration, by way of the operation wound, of tetanic toxin into the circulation. 2. The excision of the wound having suppressed all new access of tetanic toxin, it only remained to combat the toxin already fixed in the tissues.

Serotherapy in high doses gave excellent results. The doses employed were 100 c.c. of serum each day by the subcutaneous route. The injections were continued until the infection was overcome, that is to say, from ten to fifteen days. Tetanus in trench foot is always grave, and almost all the cases have been fatal. If systematic amputation of the feet is avoided, as Raymond says it should be, it is of importance to comply with the following rules: 1. To make in all cases a prophylactic injection, as early as possible, of 20 c.c. of antitetanic serum. 2. To repeat this injection, in all the cases where there has been loss of substance of the integuments, phlyctenae or eschar, at the end of eight days. 3. Not to fear, in the grave forms with extensive gangrene, infective manifestations, to increase the doses and inject 30 c.c. and more. 4. To make an injection of 10 c.c., at the least, every eight days as long as there exist sphacelated tissues, necrosed or suppurating zones—in short, as long as the wound is not in the way of definite cicatrization. 5. Not to allow an interval of more than eight days between each injection of antitetanic serum, alike to assure the continuity of the antitoxic treatment and to avoid seric or anaphylactic accidents. Thanks to this practice Raymond has had only the two cases of tetanus among several hundred serious cases treated.

22. **Standardization of Wassermann Reaction.**—Emery suggests that the Wassermann reaction should be reported in terms of Wassermann "units," the figures given by each laboratory being the same whatever the technic, and such as will indicate the number of times the serum is stronger than the weakest serum which will just give definite proof that the patient has syphilis. He suggests also that until further experience is obtained the absorption of two clear units of complement, tested in the manner described in detail in his paper, shall be regarded as a standard unit.

23. **New Technic of Heart Massage: Case of Resuscitation.**—A horizontal incision behind the left costal margin is advocated by Bost and Nerve. The abdominal incision is made 4 inches long in the median line, extending from above the umbilicus well up into the xiphosternal notch. The left costal cartilages are well retracted, bringing the anterior diaphragmatic insertion well into view. A 2 inch incision, begining 1 inch to the left of the median line, carried outward behind the costal margin, cuts the fibers of the diaphragm near their insertion. A blunt instrument pushed in opens the pleural cavity, and the opening is rapidly dilated with two or three fingers of the right hand, so that the whole hand can then be passed into the thoracic cavity anterior to the pericardium. The hand is passed upward, the thumb behind the sternum and the fingers embracing the entire organ in the pericardium. The thumb compresses the right auricle and ventricle, and the base of the heart is effectively massaged. No vessels are injured in this incision, as the superior epigastric artery is internal to the incision and passes into the rectus muscle, and the musculophrenic branch enters the diaphragm through the cellular tissue behind the eighth or ninth costal cartilages and passes backwards, deeper than the incision. The liver and stomach, even if prominent, offer no obstruction to this route, nor is the pericardium in risk of being opened. During the massage the parts can be pressed round the wrist of the operator so that air is not sucked in, and there is no tendency to collapse of the lung.

25. **"Acute Yellow Atrophy" (?) in a Munition Worker with a Pseudo T. N. T. Urine Reaction Due to Rhubarb.**—Glynn cites the case of a young woman munition worker, previous health always good, died suddenly of acute toxic jaundice (?) nine months after leaving the T. N. T. filling room. The liver, however, was much larger, more fatty, and more necrotic than in T. N. T. poisoning, and regeneration was absent. Poisoning with phosphorus or arsenic was excluded; latent T. N. T. poisoning with or without bacterial infection was almost excluded; spirochetosis icterohemorrhagica was excluded. Death was therefore probably due to "acute yellow atrophy." The pseudo T. N. T. reaction in the patient's urine was evidently due to rhubarb, rhubarb and soda having been given the patient before Glynn saw her.

1918, **5**, No. 4. Pub'd September, 1918

30 *Colloidal Nitrogen in Urine. M. Labbé and R. Dauphin.—p. 314.
31 *Lumbar Puncture in Nervous Shock. W. Mestrezat and others. —p. 327.
32 *Oculocardiac Reflex in Pleurisy. A. Mougeot and J. Colombe. —p. 345.
33 *Functional Tests of the Heart. C. Lian.—p. 358.
34 *Amebiasis on French Front. M. Bloch and C. Mattei.—p. 374.
35 *Suprarenal Treatment in Tuberculosis. R. Porak.—p. 404.

30. **Colloidal Nitrogen in the Urine.**—Labbé and Dauphin tabulate the findings from forty-one persons with various diseases and from six normal subjects. The normal average for the colloidal nitrogen was 0.128, and for the proportion of the colloidal to the total nitrogen, 1 per cent. Increase in the colloidal nitrogen is evidently an index of disturbance in nitrogen metabolism; it is pronounced in all forms of liver disease, and thus may serve in diagnosis of hepatic insufficiency. With cirrhosis of the liver, it sometimes reached 5.5 per cent. of the total nitrogen, and 6.6 with cancer of the liver. It was highest in some cases of severe diabetes, reaching 7 per cent. in one case with coma imminent.

31. **Lumbar Puncture with Nervous Shock.**—The lumbar puncture fluid was found abnormal in about 80 per cent. of fifty cases of shell concussion of the nervous system. The typical finding was the presence of from 0.35 to 1 gm. of albumin to the liter without other cell or chemical abnor-

mality, except hypersecretion. This high albumin content appears in two or three days and does not subside for weeks or months or may persist indefinitely. It testifies to the organic injury from the concussion.

32. **Oculocardiac Reflex with Pleurisy.**—Study of 37 cases of serofibrinous pleurisy, three of hemorrhagic pleurisy, five of hemothorax, three of old cured pleurisy and two of pleurisy with mediastinal lesion, confirms that the pleurisy is liable to upset the balance between the vagus and sympathetic systems. The vagus is usually the one overpowered by the other system, and this opens the portal to various serious complications.

33. **Functional Tests of the Heart.**—Lian ascribes great importance to acceleration of the pulse after a brief effort, and the length of the interval before it returns to its former rate. A one-minute run, or gymnastic treading, two a second, on the same spot, may speed up the pulse to 120 or 130, but in the normal it returns to its former figure in one or two minutes. With the heart incompetent, the acceleration of the pulse is more pronounced, and it takes longer for it to subside. If this is observed on several repetitions of the test, the heart must be considered below par.

34. **Amebiasis in France.**—Bloch and Mattei emphasize the necessity for curing carriers of amebas in the encysted form in particular as they are a source of danger to themselves as well as to others. Emetin is the main reliance but it must be given in adequate doses, although not surpassing 1 gm. as the total dose. Arsphenamin preparations may likewise prove effectual. They have examined more than 500 men with amebiasis among the active troops in France, and all but 10 per cent. of the men had never been out of France. Most of the cases were encountered in 1916; the number has been progressively declining since then. Only about 30 per cent. of the cases presented the typical symptoms of dysentery; in the others the disease might have been overlooked or ascribed to other causes if it had not been for the systematic examination of the stools. About 70 per cent. of the cases were mild, but 5 per cent. were extremely serious and tenacious.

35. **Suprarenal Treatment.**—Porak discusses the action of the medulla of the suprarenal in contrast with that of the cortex, especially when applied in treatment of the tuberculous. In two cases described there did not seem to be any reason for connecting the low blood pressure with medullary suprarenal deficiency as necropsy failed to show abnormal conditions in the suprarenal medulla. In studying the effect of suprarenal treatment he urges that not only the immediate action but the curve of the arterial pressure from day to day over the entire period of treatment and for a time afterward should be recorded. In his clinical and experimental experience, continued suprarenal treatment seemed to induce a certain depression of the heart systole and spasm of the peripheral vessels (reduction of the differential pressure). A rise in the minimal pressure in the course of treatment with suprarenal medulla is a very important symptom, indicating that the treatment must be stopped. All the experiences to date confirm that the medulla and the cortex of the suprarenals are in reality two distinct organs. They also warn that the blood pressure-raising property of the suprarenal cortex may be maintained even in Addison's disease, so that the low blood pressure cannot be ascribed to cortex insufficiency as a matter of course.

37 *Welfare Work for Mothers and Infants. Chaptal.—p. 267.
38 *Overlooked Septicemias.—De Gauléjac and Nathan.—p. 269.

36. **Physiology of Optical Illusions.**—Prompt discusses the accommodation for perspective, the perception of objects in relief, of the acute angle, etc. His conclusions as to certain features of physiologic vision suggest an explanation for a number of optical illusions, including the "canals" on Mars.

37. **Welfare Work in a Poor District in Paris.**—The efforts described have reduced the infant mortality to 2.5 per cent. The total expense has ranged from less than $300 the first year (1901), to $9,085 last year. There are over 79,000 inhabitants in the quarter, and 80 per cent. of the infants were artificially fed when the work was begun.

38. **Overlooked Septicemias.**—Summarized in Paris Letter, p. 1676.

Bulletins de la Société Médicale des Hôpitaux, Paris

July 19, 1918, **42**, No. 26

40 *Case of Pulmonary Sporotrichosis. E. Schulmann and A. Masson.—p. 776.
41 Malaria plus Echinococcus Cysts in Liver. R. Porak.—p. 780.
42 *Polyneuritis Consecutive to Arsenobenzol Treatment. Variot and Bouquier.—p. 783.
43 *Dyspeptic Coma with Acidosis. M. Labbé.—p. 786.
44 *Alcohol in Cerebrospinal Fluid. E. Lenoble and F. Daniel.—790; Id.—p. 793.
45 *Serodiagnosis of Syphilis. H. Eschbach and E. Duhot.—p. 794.
46 Liver Form of Spirochetosis. Manine.—p. 799.
47 *Folds and Fissures in Tongue. G. Railliet.—p. 802 and 804.

39. **Meningococcus Purpura.**—In a postscript to this article, Netter states that the culture features of the microbe cultivated from the infant's spinal fluid during life suggested the *Micrococcus crassus* rather than the meningococcus, and no appreciable signs of meningitis were detected at necropsy. The septicemia evidently preceded the invasion of the cerebrospinal fluid by the microbes, and such cases are becoming common, so that it is not unusual to encounter an apparently normal lumbar puncture fluid. He comments also on the increasing prevalence of purpura with meningococcus infections. In 181 cases of meningitis, 1908 to 1914, there were 2.7 per cent. with purpura, while the proportion has steadily increased since then to 29.7 per cent. in his latest series of 15 cases, out of the total 173.

40. **Pulmonary Sporotrichosis.**—The workman of 43 presented signs of pulmonary sporotrichosis seven years after apparently complete recovery under potassium iodid of a cutaneous mycosis. The cursory diagnosis had been pulmonary tuberculosis, but the right dulness suggested a pleural effusion. No fluid could be obtained by puncture, and radioscopy disclosed a large tumor in one lung with nodules elsewhere. The *Sporotrichum beurmanni* was cultivated from bloody fluid obtained by puncture in the tumor region. Schulmann and Masson know of only five cases of this disease in the lungs on record, and only in two of them was the sporotrichum cultivated direct from lung fluid. Its cultivation merely from the sputum in the other cases leaves a doubt as to the diagnosis.

42. **Polyneuritis After Arsphenamin Treatment.**—The child of 13 had been given intensive arsenobenzol treatment to ward off sympathetic ophthalmia after enucleation of one eye for glaucoma, with subsequent tumor formation in the orbit. He developed typical toxic polyneuritis and paralysis. Marie also reported the case of a girl of 13 with transverse myelitis after intensive arsenobenol treatment for manifestations of inherited syphilis.

43. **Dyspeptic Coma.**—Labbé's patient succumbed to fatal coma in the course of severe intestinal disease. There was pronounced acidosis, but this retrogressed toward the last. The reactions of acidosis were pronounced in the spinal fluid after they had disappeared from the urine. Inanition could not have been a factor as the man was getting adequate nourishment.

44. **Alcohol in Cerebrospinal Fluid.**—Lenoble and Daniel here present their third communication on this subject. It emphasizes that when alcohol gets into the cerebrospinal fluid it seems to persist there unmodified and indefinitely if aseptic conditions prevail. On the other hand, it promptly undergoes chemical modifications and rapidly disappears when asepsis is not observed, persisting at longest not over ten days. This has a medicolegal bearing in criminal cases. In a fourth communication they describe the precautions necessary for chemical examination of the fluid, and the effect on it of preceding administration of drugs.

45. **Serodiagnosis of Syphilis.**—Eschbach and Duhot advocate the use of fresh human serum, saturation of the hemolytic power, and control of the excess of alexin as indispen-

sable factors for precision in the Wassermann reaction or its modifications, as they explain in detail.

47. **Folds and Fissures in the Tongue.**—Railliet found that 188 of 308 soldiers had folds or fissures in their tongues, as also 10 of 41 children over 8. His findings suggest that ridges and grooves in the tongue may indicate the possibility of syphilis.

48. **Factitious Dermatoses.**—Dubreuilh warns among other things that even an apparently firmly dressed lesion may be artificially aggravated by a wire worked in beneath, or by some caustic injected from a hypodermic needle. He protects against the latter by introducing a sheet of zinc foil in the dressing over the lesion. The soldiers guilty of these practices are given a month or two in the guardhouse, but lately one was condemned to five years of hard labor, and the authorities are now reinvestigating some of the other cases.

49. **Urinary Spirochetosis.**—Carles relates that in some of the six typical cases described the clinical picture was that of acute nephritis; in others, hematuria was the only symptom of the urinary spirochetosis. Microscopic hematuria was the rule in all. The urine should be examined for spirochetes whenever hematuria is encountered. Urine containing red corpuscles is a favorable culture medium for spirochetes. He insisted on isolation whenever spirochetes were found in the urine. In one of the cases described, the man had apparently quite recovered from his attack and returned to duty, but hematuria returned after vaccination against typhoid, and the spirochetes appeared anew in the urine.

52. **Iodin Fumes in Treatment of Soft and Open Chancre.**—Petges and his co-workers have applied *enfumage iodé* in 236 cases of soft chancre; in eighty complicated with hard chancre. The method was described in THE JOURNAL, Aug. 25, 1917, p. 678, and elsewhere. The simple devise they prefer is a flask in which a tablespoonful of iodoform is placed and heated. One of the fine tubes in the cork reaches nearly to the bottom of the flask and is connected with a rubber bulb. The other tube is short. The flask is heated over an alcohol lamp, and the fumes are blown through the second tube on the chancre, until its deepest crevices are stained with the rest and the skin around. The lesion should be cleared of pus and débris beforehand. The *enfumage* is repeated on alternate days until the ulceration is well on the way to healing. He dresses with iodoform likewise.

August 31, 1918, **8**, No. 35

55 *Present Status of Splenectomy. E. Chabrol and H. Bénard.—p. 165.
56 *Pains of the Dyspeptic. F. Ramond.—p. 171.
57 Tardy Nevus. H. Gougerot.—p. 174.

Sept. 14, 1918, **8**, No. 37

58 *Anterior Pleurisy. Roubier.—p. 213.
59 *Radiotherapy of Cicatrices. A. Zimmern, P. Cottenot and A. Houdé.—p. 216.
60 Antisepsis for War Wounds. H. Lorin.—p. 220.

55. **Present Status of Splenectomy.**—The balance sheet for splenectomy in chronic splenomegalic jaundice shows only 10 per cent. mortality or, omitting the dubious cases, only 7 per cent. But time is demonstrating the frequency of inherited syphilis as a factor in this disease and also in splenic anemia, and the brilliant results of operative treatment should not cause this fact to be overlooked in treatment. In Banti's disease the mortality with splenectomy averages from 14 to 16 per cent.; before 1900 it was 44.4 and 31 per cent., and Chabrol cites American statistics that have brought it as low as 9.6 per cent. The splenectomies have thrown light on the functions of the spleen. In many of the patients the red corpuscles afterward returned not only to their normal number, but they regained normal resisting power. This latter new fact, Chabrol reiterates, confirms his previous assertions in regard to the spleen's being responsible for the excessive fragility of the reds. When the spleen enlarges, with no other symptoms than gastro-intestinal hemorrhages, it is possible that spleno-thrombosis may have been the primary derangement, and the enlargement of the spleen the consequence, and not the cause, of the obliteration of the spleen. Gilbert warns that gastro-intestinal hemorrhage may be the forerunner sign of venous cirrhosis of the liver. To remove the spleen to cure recurring hematemesis, as has been done recently, is certainly, Chabrol remarks, one of the most original interventions of recent years.

56. **Pain with Dyspepsia.**—Ramond reviews the indications afforded by different varieties of radiating and fixed pain in dyspeptics. He discusses their correct interpretation and the information thus derived.

58. **Anterior Pleurisy.**—Roubier describes the differential points in a case of pleurisy with an encysted serofibrinous effusion in the anterior mediastinum.

59. **Radiotherapy of Cicatricial Retraction.**—Zimmern has previously published the excellent results obtained in treatment of neuralgia by radiotherapy applied to the root nerve. With painful scars, the action is different; the rays evidently disintegrate the fibrous tissue. The latter is a pathologic form of normal connective tissue and, especially when newly formed, is susceptible to the action of the rays, like other pathologic and embryologic tissues. Any nerve fibers included in the cicatrix are relieved of compression as the fibrous tissue softens up, and thus scars that pain are promptly relieved. Even deep trunk nerves feel the effect, and sensory, motor, and trophic disturbances may retrogress. Laborde has reported rapid return of nerve functioning under radium treatment of paralysis of peripheral nerves. Others have reported cures under roentgen treatment of painful neuritis with spastic conditions, in causalgia, etc., the electric reactions returning to normal. Operative treatment was out of the question in one case described in which the nerves in the shoulder were embedded in a huge cicatricial mass. Under six roentgen exposures, a total of 30 H units, the cicatrix had become supple and the nerves gradually recuperated their functions, with even a beginning faradic reaction in the ulnar nerve. The action of the rays is more pronounced the more recent the formation of the cicatricial tissue. In conclusion, the importance is emphasized of prophylactic postoperative radiotherapy, to supplement an operation for liberation of a trunk nerve. Or it may prove useful to prepare the field for the operation, softening up the scar tissue so the nerves can be dissected out more readily. This "radiosurgical" technic is proving extremely useful. It seems scarcely probable that the nerve tissue could suffer from the exposures to the doses applied, as the nerve tissue is scarcely at all susceptible to the roentgen rays.

68 *Bacteriology of Influenza. G. Vitoux.—p. 537.
69 *War Wounds of Nerves. H. Delagenière and others.—p. 537.

61. **Purulent Pleural Effusions.**—Tuffier advocates a technic which permits the lung to resume functioning at once. Eight illustrations show the various steps. With a persisting fistula, seven or eight rubber tubes stiffened with silver wire are introduced into the cavity, one pushed up into the space above the lung. Under screen control they can be introduced into the remotest recesses of the cavity. Carrel's method of sterilization is then applied, with daily respiratory

exercises to promote expansion of the lung. The excursions of the lung can be gaged by the amount of fluid that can be injected into the pleural cavity during inspiration and during expiration. When only one microbe is found in four fields, the Carrel tubes are withdrawn and the false membrane forming a shell over the lung and its sheet of pleura is shelled off—Delorme's decortication—and the lung expands at once. He gives the details of the forty-seven cases in which these principles have been followed. There were seven medical cases, and thirty-seven chronic and three recent war wound cases. All were cured.

65. **Extensive Comminuted Fractures.**—Leriche and Policard advocate complete excision, ensuring asepsis in the focus. This is followed by repair of the soft parts by retarded primary suture the third day. Fifteen or twenty days later they proceed to whatever grafting or other operation on the bone is deemed necessary to restore the strength of the shaft. In their nine cases of the kind they did a grafting operation in four cases: forearm and tibia, and osteosynthesis, in five: humerus, tibia or radius—all successful. Comparison of the results in these cases with those under other technics has abundantly proved the benefits of this speedy triple intervention.

66. **Acute Massive Hepatonephritis.**—Intense azotemia, anuria and aberrant myeloid reaction distinguished this case of nephritis with jaundice. The man was in the hospital for three months but finally recovered after a neuritis and multiple superficial abscesses. No spirochetes were found in blood or urine at any time, but the clinical picture resembled that of exceptionally grave icterohemorrhagic spirochetosis.

67. **Screw Reduction of Fractures.**—Gentil passes a wire around the limb and then applies continuous traction on the wire, perpendicular to the limb, by means of a thumbscrew in a small frame. The traction can be spread over a large area by interposing a plaster partial cast or arranging plaster collars above and below the site. Depage has applied the same principle with a cable and weight for fractures of the femur, but Gentil shows how it can be applied to angular and overlapping fractures, etc. It usefully supplements continuous traction and immobilization, restoring normal static conditions.

68. **The Microbe of Influenza.**—Summarized in Paris Letter, p. 1676.

69. **War Wounds of Nerves.**—These addresses by Delagenière, Delorme, Walther and others were delivered at the recent French Surgical Congress at Paris.

Revue Médicale de la Suisse Romande, Geneva

September, 1918, **38,** *No. 9*

70 *Restriction of Fluids in Cardiac Edema. J. Tchertkoff and F. Heim.—p. 509.
71 *Kaolin in Treatment of Cholera. V. Kuhne.—p. 555.
72 *Dyschondroplasia. E. Kummer.—p. 569.

70. **Reduction of Fluid Intake in Treatment of Cardiac Dropsy.**—This extensive report tells of fifty cases of cardiac dropsy systematically treated with reduction of fluid and of salt. This alone may restore conditions to clinically normal or, if not, it materially reenforces the action of heart and kidney tonics, restoring compensation except in the absolutely doomed cases. The Karell treatment is on the same principle, but it represents unnecessary deprivations. Tchertkoff and Heim gave a light nourishing diet of 2,000 calories but with only 700 or 900 gm. of fluid and no salt in the bread. The patients do not object to this diet for a week; after this it is modified to allow 1,500 or 1,800 gm. fluid and 2.5 gm. salt with 2,500 calories, but no meat. This fluid-poor and salt-poor diet is less distasteful the more pronounced the dropsy; that is, it is tolerated better, the more urgently it is needed. The weight, the daily diuresis, the rhythm and frequency of the pulse, the blood pressure and the refractometer findings in the blood were compared systematically in all the cases. All presented symptoms of edematous asystoly, dyspnea, cyanosis, congestion in lungs and liver, oliguria and dilatation of the heart. In eighteen, no drugs were required, and clinical balance was restored within the week by the dry diet and repose alone. The patients were from 30 to 80 years old. One lost 12 pounds in five days, and several voided 3,000 c.c. of urine in twenty-four hours, with an intake of fluid less than 600 or 800 c.c. All left the hospital with earning power restored. They report further three exceptionally severe cases in which the fatal outcome could not be warded off in this way, but improvement was marked even in these cases. In all the other cases, the dry diet had to be reenforced with drugs to act on heart and kidneys. They review the literature on the subject, and theorize to explain the efficacy of restriction of fluids. Salt has to be restricted likewise, to enable the patients to bear the reduction in fluids, and especially because the kidney functioning is usually below par in these cases. Repose is an important element in the treatment, perhaps the most important of all. The reason why this is not generally appreciated is because drugs are usually given at once, without waiting to watch the effects of repose and dieting alone. They make a point of refraining from drugs, even a purgative, during the first few days. If there is a tendency to uremia, the diet has to be poor in proteins.

71. **Cholera.**—Kuhne declares that with kaolin treatment the mortality of cholera was reduced from 45 or higher to 2 or 3 per cent. in his extensive experience in Serbia. All the other physicians had similarly favorable experiences, and the authorities provided large stores of kaolin for immediate use as occasion arose. This method of treating cholera, etc., by drinking large amounts of suspensions of kaolin was introduced by Stumpf several years ago, and has been repeatedly described in these columns. It is said to be entirely harmless, and given at the first symptoms cures in twenty-four hours. Kuhne reiterates that even apparently moribund cholera patients may be saved by it. If too weak to swallow, 3 liters of the constantly stirred suspension can be injected into the bowel. The kaolin is useful in all forms of diarrhea, so that even if the diagnosis has been incorrect, benefit will result. When skeptics protest against this *médication bolique,* Stumpf merely says: "When you have experienced what bolus alba is capable of, then you can talk, but not before."

72. **Ollier's Disease.**—Kummer gives a detailed illustrated report of a typical case of dyschondroplasia in a young woman.

Correspondenz-Blatt für Schweizer Aerzte, Basel

75 Isolated Traumatic Paralysis of Suprascapular Nerve. J. Dubs.—p. 1305.
76 *The Swallowing Reflex from the Cornea. J. Strebel.—p. 1311.

73. **Superheated Air as Aid to Surgery.**—Iselin lauds the benefit from application of superheated air in treatment of acute inflammations, accidental wounds, and to promote drainage of the peritoneum. Applied at once after early surgical clearing out of the wound it wards off infection. He uses the ordinary hot air frame or cradle but has an electric device to heat the air.

76. **The Swallowing Reflex from the Cornea.**—Strebel has noticed that when the surface of the eye is bedrizzled with some indifferent fluid, such as saline, there is a reflex swallowing movement in addition to the reflex lid closing and the withdrawal movements. This swallowing reflex is apparent even in the newly born if cold water is used. He found it pronounced in 85 per cent. of 500 persons tested. Its absence indicates lack of sensibility in the cornea, and this was the case in eleven cases of herpes of the cornea in 1916 and also in a recent series of seventeen cases of influenzal herpes of the cornea. It was impossible to elicit the swallowing reflex in these cases.

79 *Methylene Blue Reaction in the Urine. C. B. Farmachidis.—p. 574.
80 Treatment of War Wounds. G. B. Ricci.—p. 578.

77. **The Nitrogen in the Urine.**—Pittarelli describes an improvised apparatus with which it is possible to apply the Kjeldahl procedure to determine the "azoturic ratio," that is, the exact proportion of nitrogen eliminated in the urine in the form of urea.

78. **Ankylosis of Upper Jaw.**—Vecchi remarks that after a fall on the chin, temporomandibular ankylosis may develop on both sides, but with direct trauma it is unilateral, even when the jaw has been long immobilized. Forcible correction of the ankylosis is of little use as the ankylosis soon becomes established again. Even osteotomy does not give permanent results. He gives the details of a case to show the good and durable effect of resection with interposition of a muscle flap. Any operation of the kind should be done with everything ready for an emergency tracheotomy at need, but it is not necessary to make a preliminary tracheotomy if the tongue is fastened with forceps or a thread, so that the tongue cannot slip back into the throat. After the operation the jaw should be actively and passively exercised; a wooden wedge between the teeth is useful for this. These exercises have to be kept up for months and years as the tendency for exuberant callus production may long persist, especially in the young and vigorous.

79. **Methylene Blue Test for Bile Pigments in the Urine.**—Farmachidis states that methylene blue reveals the presence of bile pigments in the urine, by a change in tint to a grass green, on addition of 5 drops of a 1 per cent. solution of methylene blue to about 5 c.c. of the urine. If there is only urobilin present, the tint is more of an emerald green. With other substances in the urine the tint remains the unmodified blue.

89 Present Status of Cranioplasty. E. Aievoli.—p. 693.
90 The Significance of the Habitus Phthisicus. A. Ferrannini.—p. 694.

81. **Coexistence of Renal and Genital Anomalies.**—Guizzetti found congenital anomalies in the kidneys in 6 of 1,187 female cadavers and in 9 of 1,653 males. In 7 of the total 2,840 cadavers, one kidney was missing. In a previous series reported, one kidney was missing in 39 of 20,000 cadavers. In his last series, in one-third of the 15 cases of renal anomalies there were also anomalies in the genital sphere. This suggested the possibility that the discovery of genital anomalies might turn the scale in favor of the assumption of some renal deformity in dubious cases. In 14 cadavers he found that the vas deferens on one side was missing, and in 4 others it was defective. In these 4 the anomaly could not have been detected by clinical examination, but in the others the absence of the vas deferens could have been readily ascertained by palpation of the spermatic funiculus. In this group of 14, the kidney on one side was missing in 7; in one there was a horse-shoe kidney, and in the other 2 the kidney was not in its normal place; only in 4 were the kidneys apparently normal at birth. Among 12 instances of one missing kidney, therefore, the vas deferens on that side was missing likewise. Palpation of the spermatic cord would easily have revealed this during life. Especially with normal ureter openings in the bladder, the discovery of anomalies in the vas deferens might prove the warning signal to prevent nephrectomy when there is only one kidney. Anomalies of the kidneys seem to be more frequent in men than in women. By comparing the palpation findings on the two sides it is a simple matter to detect the absence of the vas.

102 *Anthrax Vaccine in Treatment of Leprosy. J. M. Campos.—p. 251.
103 Professional Ethics. O. Montoro.—p. 252.

100. **Formation of Bone in Penis.**—The man of 50 refuses to allow operative removal of the long narrow strip of bone tissue visible in roentgenoscopy. In another case there was induration of the corpora cavernosa but no actual bone formation; under roentgen treatment, the induration retrogressed. Neither of these men had had known venereal disease. In the following number A. Lutz relates that formation of bone in the penis is physiologic in certain species of monkeys, and cites considerable bibliography. He has never heard of a case in the human before.

102. **Treatment of Leprosy.**—Campos writes from Colombia to call attention to the "truly remarkable improvement" in two cases of leprosy in which an anti-anthrax vaccine was given systematically. The bacillus of lepra seems to be unable to survive the action of the toxins elaborated by the anthrax bacillus. He injected lepra patients with cultures of the anthrax bacilli. This seemed to modify the tissues in such a way that the lepra bacilli soon perished. The rapid improvement was paralleled by the disappearance of living bacilli from the field until no further active bacilli could be found in specimens of lymph and nasal secretions. Campos urges others to give this simple and inexpensive biologic treatment a trial. The dose each time was 0.5 c.c. of the liquid vaccine against bacterial anthrax, obtained from the Pasteur Institute.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

Aug. 17, 1918, 2, No. 7

104 *Glycolysis in the Blood. J. Hekman and A. van Meeteren.—p. 497.
105 Influenza. B. M. van Driel.—p. 513; J. J. van de Velde.—p. 517; G. F. Wesenhagen.—p. 521.
106 *Electric Reactions in Children. J. B. Stalling-Schwab.—p. 514.
107 Scarlatinal Ethmoiditis; Three Cases. W. Schilperoort.—p. 522.

104. **Glycolysis in the Blood.**—Hekman and van Meeteren describe a micromethod with which it is possible to estimate the sugar-splitting property of the blood. Over sixteen pages are devoted to the history of the subject, description of their research, and the results realized. Their technic is based on Bang's method, using 0.5 gm. sugar, dissolved, on Bang filter paper, drying at 100 C., adding 0.1 c.c. of blood, and leaving it in contact with the sugar for two hours. The sugar content of the blood is known and the difference between the findings before and after the test shows the amount of sugar that has been split. The paper is placed in a cylindrical glass, open at both ends; this is placed in a test tube, the lower end resting on a marble in the tube. A minute amount of blood answers for the test, and the whole blood is used; the findings corresponded always with those of other tests and methods. In order to ensure greater precision they improvised a device to regulate the gas pressure for the Bang titration procedure, as they describe.

Among the practical results obtained was the demonstration that the glycolysis in the blood is no index of pancreas functioning. The sugar-splitting property of the blood kept abnormally high in a dog after removal of the pancreas. In diabetes, the glycolytic power was abnormally low in the graver cases. By dividing the figure representing the sugar content of the blood, with the figure representing the glycolysis, we obtain a quotient which represents the sugar-splitting coefficient of the blood. This coefficient varies very little in normal persons, never going above 1.5 or below 0.7 in their experience, so that 1 may be accepted as the normal. In diabetes, this coefficient runs up very high, to 6 or above. Comparison of series of coefficients shows that this increased glycolysis is a compensatory function which strives to get rid of the excess of sugar in the tissues (including the blood). But this compensating process is not complete; the glycolysis does not increase parellel to the increase in the sugar content of the blood. Especially in the graver cases, this compensating function is defective, and sometimes there is no sign of it, the glycolysis figure being actually below the normal figure. This of course is an unfavorable sign; if the glycolysis increases under treatment this modifies favorably the prognosis.

The findings in cases of defective or perverted functioning of the thyroid, parathyroids and pituitary body also suggested the possibility that this abnormal functioning might be an important factor in the pathogenesis of diabetes. When glycosuria without ketonuria is encountered, and the glycolytic power of the blood is found abnormally low, the possibility of a thyrogenous or pituitary origin should be borne in mind. They expect to continue research on the influence of thyroid treatment, of epinephrin, etc., on the glycolysis in the blood, but at present they merely report the facts they have established, for some of which they have no explanation as yet to offer.

106. **Electric Tests on Children.**—Stalling-Schwab reports from the Emma Children's Hospital at Amsterdam the findings with electric tests applied to thirty-nine children free from manifestations of spasmophilia, and to forty-eight who presented symptoms of tetany. She compares the findings with what others have reported in this line. They confirm that these two groups of children respond quite differently to electric tests, and also to treatment by dieting and calcium, phosphorus and cod liver oil.

Hospitalstidende, Copenhagen

Aug. 21, 1918, **61**, No. 34

108 *Operative Treatment of Tuberculosis of the Spleen. E. Petersen. —p. 1105. Comenced in No. 33, p. 1073.

108. **Tuberculosis of the Spleen.**—Petersen insists on the necessity for removal of a tuberculous spleen at the earliest possible moment, even if there may be tuberculous lesions elsewhere. The tuberculous spleen leads inevitably to death unless it is removed in time, while a complete cure is possible after splenectomy if no other organs are involved. He devotes eleven pages to tabulation of the details in twenty-one operative cases, including one from his own experience. The mortality was 25 per cent., but 60 per cent. were cured when last heard from. The findings are tabulated also from twenty-three cadavers with tuberculosis of the spleen. The differential diagnosis is based on the chronic course, the personal and family history, and the enlargement of the spleen with little if any tenderness, but there are about a dozen other diseases that have to be excluded first, from leukemia, hemolytic jaundice, polycythemia, and anemia to malaria, cysts and abscesses. The chief difficulty is in excluding pseudoleukemia and polycythemia. Banti's disease calls for splenectomy likewise. Even at the laparotomy, differentiation may be difficult. Hayden in one case merely curetted and drained, but this is permissible only when total splenectomy is impracticable. Quénu and Baudet in one case found a tuberculous abscess in the lower pole, and they were able to marsupialize it, suturing the spleen to the incision in the parietal peritoneum, so that the abscess could be incised and cleared out, all outside the peritoneum. Recovery was complete in four months. In the advanced necropsy cases, the spleen weighed up to 4 pounds, 3,780 gm., or measured 27 by 19 by 16 cm. in some of the cases.

Norsk Magazin for Lægevidenskaben, Christiania

September, 1918, **79**, No. 9

109 *Insanity in Norway. M. Holmboe.—p. 977.
110 *Intracranial Sympathetic Paralysis. G. Ræder.—p. 999.
111 *Sanatorium North of Arctic Circle. T. Neumann.—p. 1017.
112 Public Health in Norway in 1740. J. Anderssen.—p. 1038.

109. **Insanity and Feeblemindedness in Norway.**—This review of the 1910 census supplements Holmboe's two previous works of the kind on the census of 1890 and of 1900. In 1900 the insane numbered 2.63 per thousand inhabitants, and in 1910, 3.13 per thousand. He advocates compulsory registration of all the insane and feebleminded.

110. **Intracranial Sympathetic Paralysis.**—Ræder's patient had a tumor between the internal carotid artery and the gasserian ganglion. Besides headache, vomiting and pains in the region innervated by the left trigeminal, there had been paresis of the left side of the palate, miosis, ptosis and reduced intra-ocular pressure, but there were no vasomotor or trophic disturbances and no enophthalmos.

111. **Far Northern Sanatorium.**—The Vensmoen institution described is within forty miles of the Arctic Ocean, thirty miles north of the Arctic circle. It is a state sanatorium, with accommodations for fifty-four tuberculous of each sex. Of the total 257 given treatment since it opened two years ago, a favorable result was evident in 72.77 per cent., although nearly 35 per cent. of the patients were in the third stage of tuberculosis. In winter the sun is above the horizon only for one hour and thirty-seven minutes; in summer the sun is below the horizon only for six hours.

113 *Congenital and Inherited Zonular Cataract. K. Lehmann.—p. 1443. Commenced in No. 36, p. 1407.

113. **Inherited Cataract in Danish Family.**—Lehman has been investigating the Volkmann family, tracing the tendency to zonular cataract through four generations. The cataract was bilateral in nearly all those affected. Its occurrence did not indicate that it was inherited as a mendelian dominant, but on the other hand there was nothing positive to disprove this. Epilepsy and idiocy were not unusually common in this family, but the poor eyesight reduces the level of the environment. Of the sixty children or young persons in the various branches of the family, twenty-five had cataract, and four of these had had convulsions and two rachitis. The color of the hair, eyes, the height, chest measure, etc., did not display any special inherited features paralleling the cataract. The best results in treatment were with repeated small discisions. In one, vision is 6/6 although two operations were done at 14 and 16 years of age. The danger of infection is minimal with this small intervention. The patients must be supervised to detect the first onset of glaucoma.

OBSTETRIC SCIENCE AND ART IN THE SERVICE OF THE NATION *

EDWARD P. DAVIS, A.M., M.D.
Professor of Obstetrics, Jefferson Medical College
PHILADELPHIA

At the present time no medical problem in the United States is without its bearing on the winning of the war and the maintenance of the strength of our population. It is pertinent to ask, What has modern obstetric science and art to give to the nation, and how may it best be given and most efficiently used?

Among the recent advances in obstetrics there are measures which may be rightly called medical and others which are surgical.

MEDICAL ADVANCES IN OBSTETRICS

In the first, agencies to relieve pain during parturition and to prevent suffering and shock are easily of the first importance. The combination of the treatment by suggestion, discipline, morphin and scopolamin, known as the twilight sleep method, has largely collapsed in its gaseous elements, but we have a true knowledge gained by experience of its real value. Those who have used it most intelligently say that when a patient is in a hospital under the constant attention of an experienced physician and good nurses, during the first stage of labor and the early part of the second stage, morphin and scopolamin may be used to advantage. In highly nervous patients it is impossible to tell in advance whether this combination of drugs will excite or soothe the patient; there is some danger of producing asphyxia in the child, labor is prolonged, and the use of forceps rendered more often necessary. This method has elements of value within a narrow scope; we recognize in it a tried and familiar friend in morphin, which practitioners have used during the first stage of labor for many years, with success.

Nitrous oxid and oxygen are strongly recommended and have enthusiastic advocates, but observation and experience show that their use requires skill and experience, that some patients are partially asphyxiated and greatly irritated by these gases, and that they are not suitable for surgical procedures or prolonged anesthesia. They are of especial value for brief manipulations, such as the introduction of bougies or the inducing of labor, the use of dilating bags or the introduction or removal of gauze packing.

But these more recent attempts to mitigate the suffering of parturition have done much good because they have directed the attention of physicians to this point and have resulted in a classification of our knowledge and a comparison of methods. We know that during the first stages of labor, morphin or codein with atropin is exceedingly useful in promoting dilatation with lessened suffering. When nervousness only is the complication, bromids are sometimes of value. During the actual second stage, nitrous oxid and oxygen are used successfully if properly given, and ether is exceedingly valuable when quickly inhaled in small quantities. By such use of ether the mother is rendered unconscious at the moment when the child is born, waking quickly and with no bad results. No woman should pass through labor without intelligent and careful effort to reduce her suffering to the lowest possible degree. In this regard the women in the United States have for years had better attention than is usually given to European women.

Pituitary solution was hailed as a substitute for forceps, the great time saver for the busy practitioner and a great remedy for delay in labor. Its unwise use has caused rupture of the uterus, severe lacerations in the mother and death of the fetus through pressure. It has a distinct and limited field of use. When the mother and child are proportionate in size and the head is low down in the pelvic cavity or on the pelvic floor, the cervix completely dilated and all that is needed is a few uterine contractions, then, and only then, should pituitary solution be given during labor. To cause the empty uterus to contract quickly, thus checking hemorrhage, pituitary solution is especially valuable: it may be used at cesarean section for that purpose or for the immediate stoppage of sudden and threatening bleeding. For hemorrhage it should always be followed by strychnin and ergot, as its effects are brief. In paralysis of the intestine following abdominal section or complicating the puerperal period, pituitary solution is often of value.

The treatment of puerperal septic infection by vaccines and serums is in line with modern advances in the treatment of other diseases. So far there has been no proved ground for the belief that vaccines and serums are of special value in combating puerperal septic infections. Antistreptococcic serum, to be effective, must be prepared for each case and given in doses so large that it may seriously depress the patient; vaccines have yet to prove their reliable effect. What is, however, of decided value and what can do no harm, is sterile horse serum, which in the toxemia of pregnancy and the puerperal state, may be given in doses of 20 c.c., with excellent result. This substance increases the mother's resisting power without producing depression.

The toxemia of pregnancy in its early stage of pernicious nausea and vomiting or in its later form of

---

* Read before the Tri-State Medical Association, Madison, Wis., Aug. 20, 1918.

eclampsia, with or without convulsions, *remains* an undiscovered country and an unconquered field for advance in obstetric science. It has been clearly shown that the indiscriminate delivery of eclamptic women by *vaginal or abdominal* section is worse than useless. The emptying of the uterus by no means ends the danger. That form of treatment which secures rapid and thorough elimination with the least shock is best. To be avoided are depressants, as narcotics in large doses. In rare cases prompt delivery by section is indicated. To put the matter more in detail, it is my habit in these cases to bleed, followed by intravenous saline transfusion; to irrigate thoroughly the stomach, leaving within it calomel and soda; to irrigate thoroughly and copiously the intestine, leaving salt solution for absorption; to cleanse the patient's skin and place her between blankets; to use no anesthetic; to give abundance of fresh air and if available, oxygen by inhalation; not to interfere with the uterus unless labor begins, and then if it delays, to empty the uterus in the most prompt and least disturbing manner.

Cesarean section, vaginal or abdominal, is most successful in fulminant toxemia before convulsions begin. When treatment by elimination has failed to improve the patient's condition, prompt delivery may turn the scale.

Convulsions are of minor importance; a woman may die without having a convulsion and another recover who has had a hundred. The prognosis of severe toxemia, whether in early or in late pregnancy, is absolutely uncertain. It resembles strongly the prognosis in pneumonia. In both diseases, death comes from toxemia, and one cannot accurately recognize or *isolate the toxins*.

ADVANCES IN OBSTETRIC SURGERY

Obsetric medicine, then, has gained in its ability to lessen pain and shock, to shorten tedious labor, to prevent sudden hemorrhage and rescue the mother from the dangers of toxemia; but obstetric surgery has shown more decided advances. Contracted pelvis is one of the least dangerous of obstetric complications when the patient is in good hands. A thorough knowledge of obstetrics will prevent postpartum hemorrhage in a great majority of cases. The immediate repair of lacerations of the cervix, anterior and posterior segments of the pelvic floor and perineum gives the patient a complete anatomic recovery from labor. The prompt performance of abdominal cesarean section will save the lives of mother and child in many cases of placenta praevia. Abdominal and pelvic tumors complicating pregnancy and labor are successfully removed; ectopic gestation and rupture of the uterus call for prompt and efficient obstetric surgery. The high application of forceps, prophylactic version in contracted pelvis, craniotomy on the living child, and violent methods of dilation and delivery in prolapse of the cord and shoulder presentation have been abandoned. In no branch of surgery has greater advance been made than in obstetric surgery.

And yet, when a general survey is made of the field of obstetric practice, a very striking fact becomes apparent. Parturition is today to the women of the United States only less dangerous than cancer and tuberculosis, and this extraordinary condition depends on the prevalence of puerperal septic *infection*. Among the civilized nations of the earth, the United States has an unenviable position in the occurrence of puerperal septic infection. Time need not be lost in stating statistics, but these facts are abundantly proved. What is their explanation? Unquestionably the best American obstetrics is the best in the world. In other words, when an American woman has the benefit of the best special practice in obstetrics during pregnancy and labor, she receives more careful, thorough and painstaking care than in any other country. Those who have watched foreign clinics and are familiar with the literature of these clinics have observed this fact.

The worst American obstetrics is probably the worst in the world, and the explanation of this condition lies in the fact that such practice is done by ignorant and often unscrupulous and careless physicians. In Europe the trained midwife is far safer than in this country the bad American doctor. We in America have no use for the midwife and do not desire a perpetuation of her species; we believe that the profession of this country should do its obstetric practice and do it well; but unquestionably a thoroughly trained European midwife is far more efficient and safe than the worst type of American doctor. What suggestion can be made to remedy this state of affairs?

American surgery has reached its present world preeminence through the native skill, ingenuity and originality of the surgeons of the United States. They have been greatly aided by the multiplication of hospitals and by securing from the community in which they are, abundant opportunity for surgical practice and research. Our people have become educated to demand the very highest grade of surgical skill; conditions calling for surgical treatment are well understood by the laity; people are familiar with hospitals and their advantages, and a surgical operation is neither uncommon nor fearful.

If we apply to obstetrics some of the same lines of development, we shall find that the multiplication of maternity hospitals will be of the greatest possible service to our people and to our profession. To these hospitals should be taken primiparous women and all others having complications. If this cannot be done, then the public should demand that the essentials of hospital care be given in the *home of the patient*; in other words, that in her home she *has special obstetric skill*, trained obstetric nursing, *skilled anesthesia*, and whatever apparatus or instruments are necessary for a competent surgical and aseptic management of her case. If the poor can be properly treated in the hospital, if those that are well-to-do can be properly accommodated in hospitals, and if those that are able to demand and afford competent obstetric care can secure it in their homes there will be a definite and great improvement. This will result in the better education of the profession in obstetrics, the better education of the laity, and improved training for nurses as well. The wear and tear of human life may be considerably prevented by such measures. Good roads and motor vehicles and a sufficient number of maternity hospitals will make it possible for the prompt transfer of complicated cases to receive proper attention.

Among the most interesting problems that engage the attention of the modern obstetrician is infection by the *Bacillus coli-communis*, complicating pregnancy and the puerperal state. This frequently manifests itself first in the appendix and with almost equal frequency in the gallbladder. During pregnancy the appendix should be removed as soon as it gives evidence of disease; and the earlier in pregnancy this is done, the better. A gallbladder that is a constant source of suffering and danger should be drained or extirpated as early as possible in pregnancy. The obstetric surgeon is the best man to do this, because experience and observation will help him to detect signs of danger that others may pass unnoticed. A third form of this infection is that which attacks the pelvis of the kidney. Here in pronounced cases incision and drainage of the kidney are followed by the recovery of the patient without the interruption of pregnancy. This subject presents a most interesting and satisfactory field for further study by the obstetrician.

IMPORTANCE OF A CORRECT DIAGNOSIS

When, however, this subject is under discussion, the general practitioner asks where he comes in. He has been told that obstetrics is his specialty; he has long soothed his conscience and the minds of his patients by describing labor as a physiologic process, which therefore requires little or no supervision. This is a half truth more dangerous than a lie; labor is a physiologic process in the physiologic individual, but never in the pathologic person. How many sound, healthy women do we see in practice? How many sound, healthy men are married to these women? There is nothing so perfect as Nature's methods in pregnancy, labor and the puerperal state in a sound woman who is anatomically and physiologically perfect; but of such I have seen very few. There is for the general practitioner one of the most important, interesting and lucrative specialties in medicine. It is that of diagnosis. If people are not very sick and he can find it out, they need very little treatment and will recover. If they are very ill, they frequently require in the surgical way attention that he cannot give; but he is the one who first sees the patient. On his diagnosis may depend the life of the individual. A correct diagnosis promptly made calls for the prompt performance of the operation which is successful; a failure in diagnosis and delay lose the patient's life. Nothing is better appreciated by the laity than diagnostic ability on the part of their physician, and the general practitioner who is skilled in diagnosis becomes the honored and trusted adviser of the family. He may not treat its members for many of their disorders, but his verdict for the necessity of treatment is received without question. In obstetrics, diagnosis is of paramount importance; we are accustomed to tell our senior medical students at the Jefferson Medical College that we hope that a kind Providence will prevent many of them from performing major obstetric operations. But we expect and demand that all of them shall learn obstetric diagnosis, and that they shall learn to know when the head of the child has entered the pelvis and when it remains at or above the pelvic brim. To recognize the normal and equally to recognize the abnormal is no small achievement in any branch of medicine. The man with a large general practice cannot do much obstetric work and do it well without injuring his general medical practice; and many general practitioners do obstetrics to keep the medical practice of the family, a most unwise arrangement for physician and patient. The general practitioner may be tempted to yield to the pleas of his patient to undertake their obstetric care when he realizes that he has neither the time nor ability nor inclination to do the work well.

There will be no essential diminution in the mortality and morbidity of puerperal septic infection until complicated cases of obstetrics are considered as important, as dangerous and as imperative as appendicitis, infection of the gall bladder, or other acute and serious abdominal conditions. Then, and only then, will the general practitioner abstain from fruitless efforts to deliver, and a competent obstetrician will be summoned at the very first sign of danger during labor.

The maternity hospital will afford skilled attention, aseptic care to a large portion of the community, well-to-do and poor; and when our people are educated to the importance of the complicated confinement and the necessity for securing skilled attention for these cases, there will be a decided improvement.

RÔLE OF OBSTETRICS AFTER THE WAR

The present war has drawn attention to the importance of obstetric science and art. The French have gone very thoroughly into the question of what can be done to conserve the French nation. In this country the necessity of prenatal care is being manifested, and the enormous wastage of human life is drawing attention to the necessity for saving. Hitherto the value of a human life has been rated at its wage-earning capacity; hence the sentimental verdict of a jury which, to save the feelings of the parents, awarded damages of 39 cents for the life of a child run over and killed by a car.

When the present conflict of arms ceases there will follow a second struggle no less earnest, no less determined, no less important, no less vital; it will be a struggle among the nations of the earth for supremacy in commerce, manufacture, science and all essentials in the life of a great nation. That people which is strongest and most sound physically, mentally and morally will do best and win most; hence the United States needs a strong and most vigorous population for future developments.

There is another and deeper significance to this question: Death and destruction have been spread abroad throughout the world; many households have been permanently saddened. One recalls the famous utterance of John Bright in the House of Commons, "The Angel of Death is abroad among us, one can almost hear the beating of his wings." Casualty lists will grow longer in these United States, and there will be more gold stars before this war is over.

But the child in the world has always been the symbol of hope. Many a sorrow has been lessened by the love of children since the time when in the temple a Child was placed in the midst of the people. And so the children of our country may well become the silver lining to the present cloud.

250 South Twenty-First Street.

The Victory Over Rabies.—During the year 1916, according to a report recently issued, 1,008 persons from the district of Lyons received the antirabic treatment at the bacteriologic institute in that city. (Rochaix, A.: Le traitment antirabique dans la region Lyonnaise [1916], *Jour. de physiol.*, 1918, **17**, 692.) A single death in this list places the mortality at 0.099 per cent. Since 1900 more than 9,000 persons have received antirabic inoculations at Lyons alone, with a total of nine deaths, or 0.09 per cent. The story has become an old one; but it will long bear repetition as an eloquent testimony of the blessing of intelligent scientific research.

OTOLARYNGOLOGY IN THE FIRST YEAR OF THE WAR

AN INFORMAL REPORT *

HARRIS P. MOSHER, M.D. (Boston)
Lieutenant-Colonel, M. C., N. A.
WASHINGTON, D. C.

The subjects dealt with in this informal paper are: the medical problems of the base hospitals at the cantonments, and some gossip about the personnel at these hospitals; the present and future needs of otolaryngology as to personnel and finally a few comments on the character of the medical work in the Army, stating why I believe it a grown man's work and not, as it has been dubbed by a few of the present stay-at-homes, work to be done by boys.

My duty up to the present time has been largely in recruiting medical officers for otolaryngology. This naturally has aroused deep feeling, and the closing paragraphs, I am conscious, are at least reminiscent of this feeling.

THE MEDICAL PROBLEMS OF THE CANTONMENTS

The cantonments, as is well known, are small cities with a population of from 20,000 to 40,000. Although they were built in a few months, they have all the appointments of cities of years of growth, from churches to jails, and from libraries and theaters to fire engine houses. They are cities of youth; poverty and old age are never seen. Except for the nursing staff, women play but a minor part in them. In the normal cycle of a man's life, death alone is present.

At these cantonments there are sixteen base hospitals for the National Army and fifteen for the National Guard. Besides these there are scattered over the country general hospitals, post hospitals and special hospitals. One of the special hospitals is being fitted out as a hospital for head surgery. Reconstruction hospitals and hospitals for reeducation are soon to come. The number of beds in the cantonment base hospitals carries between 1,000 and 2,000, the beds in the general and post hospitals from 150 to 500. One special hospital for tuberculosis has 1,000 beds, and the hospital for head surgery has a maximum capacity of 500. Up to the present time the total number of beds planned for in this country is more than 70,000. I am not at liberty to give even approximate figures, such as the ones just given, for the hospitals contemplated and actually built abroad, but the American public can rest assured that there will be an adequate number.

The death rate is of course low, for the soldier citizens of these cantonments were chosen as physically fit before they took up residence there. The sick rate also should be low, and is low; but a curious fact, well known to all experienced medical men in the Army, soon became evident—namely, that the assembling of these apparently well young men was at once followed by epidemics of disease. The infectious diseases of childhood at once appeared and took a very virulent course. Pneumonia, the friend of the old, became the deadly enemy of youth. Cerebrospinal meningitis, which is relatively rare in civil life, became almost common.

An apparently well man is often a carrier of bacteria which he gives to his fellows. Men who have long lived together, however, seem to acquire an immunity to each other's bacteria; but take men who are strangers and assemble them in large numbers, as they are today assembled in the cantonments, and infectious diseases at once appear in spite of the healthy mode of life. Infections borne by food and drink—for example, typhoid fever, have been practically stamped out. Breath-borne infections, the bacteria of which live in some part of the respiratory tract, preferably the nose and throat, are yet to be conquered.

There are no vaccines for most of these diseases. The fundamental point in dealing with them, therefore, is to prevent them by avoiding overcrowding and by providing adequate ventilation. Recurring epidemics of cerebrospinal meningitis which took place last year at the barracks of one of the most celebrated regiments in England were controlled by such measures. The sleeping huts, which previously contained thirty beds, had ten beds taken out so that the minimum distance between the beds was 2½ feet. In addition, half of the windows of each hut were opened at the top on a slant and nailed in this position and untouched regardless of the weather.

As the men come to the camps well, the problem is to find at once the soldiers who are carriers of disease and isolate them before they can infect their mates. This was accomplished in a dramatic fashion at one cantonment recently by having twenty-four teams of medical men meet the incoming troop trains and take cultures from the nose and throat of each recruit. Those who were found to be carriers were at once isolated and treated. Work of this kind means that the bacteriologists in this war are an overworked set of men.

The problem of the carrier is the acute medical problem of the cantonments. It is becoming evident that the nose and throat are the abode of choice of the streptococcus and probably of the organisms responsible for many of the infectious diseases. The prophylaxis of infections of the respiratory organs is a most pressing problem in this country and abroad. Striking results in the control of infectious diseases have been obtained in at least one cantonment by the use of gauze masks, and in measles the use of the gauze mask has been made compulsory. Only the surface of this problem has been scratched. Never before has such an opportunity been offered to solve it. If it can be solved it will be one of the great medical achievements of the war. The poisonous gas of the enemy can be seen. We take the elaborate masks which are used by the soldiers to protect themselves as a matter of course. The germ-laden breath of the soldier cannot be seen, but it is even more deadly than the gas. It would cause a smile if every soldier on a transport was required to wear a gauze mask when below or between decks, or if a less novel measure was ordered, namely, that every soldier should carry a piece of gauze and be required to cough into it. Had either of these measures been a routine procedure on the transports last winter, my feeling is that instead of the men landing in France ill with acute or chronic pharyngitis, acute or chronic tonsillitis or acute or subacute bronchitis, which was the condition of things all through last winter, the percentage of such diseases would have been markedly reduced. I feel strongly on this point, and I am certain that I am not making a mountain out of a mole hill.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

In addition to the problem of the carrier at the base hospitals, there have come up for solution the control and prevention of venereal disease, the treatment of infectious diseases and of diseases of the respiratory tract, and the treatment of the surgical complications of these diseases, such as tonsillitis, mastoiditis and empyema. The otolaryngologist, the general medical men, and the bacteriologists have been by far the busiest medical officers. Waves of infection have passed over some of the cantonments, and the streptococcus has had a field day.

OPERATIONS PERFORMED IN EAR, NOSE, AND THROAT DEPARTMENT, HEAD SECTION, SURGICAL DIVISION, BASE HOSPITAL, CAMP SHERMAN, OHIO, IN APRIL, 1918

* No operation has been other than successful.

Only supposedly well men are chosen for the Army because its sole purpose is to fight. The chief purpose of the Medical Corps, therefore, is to keep the soldier well. Unfortunately, it is not its sole purpose because well men get sick, and fighting men must be injured. Naturally, the most dramatic part of the medical officer's work in the Army is caring for the wounded, the most important part, however, is keeping the fighting men well. Preventive medicine, therefore, is the medical problem of the Army *par excellence*. Those who have the vision to engage in the solution of its problems have under their control in the Army an unparalleled human laboratory and the opportunity of a century. I feel that medical men do not as yet realize this.

If practice makes perfect, the otolaryngologists in the Army today should be experts in opening peritonsillar abscesses, in resecting the septum, in tonsillectomy and in mastoidectomy. They can never hope, however, to catch up with the number of tonsils that are acting as foci of infection and thermostats for streptococci. The dentists can never hope to clean up all the teeth that are foci of infection, and the surgeons, operating as they do in some of the cantonments in from ten to twenty cases of hernia a day, can never see the end of their task. It is my belief that the soldiers who are to compose the standing army which is to maintain peace when it finally comes will never take their place in the ranks unless they have normal noses and throats, or have them made normal by operation.

The total number of treatments given in the head house of the base hospital at Camp Sherman, Chillicothe, Ohio, during the month of April, 1918, was 6,174. Of these, 1,755 were given in the eye section and 4,419 in the ear, nose and throat department. The report of the operations in the ear, nose and throat department of the head section is given in the accompanying table. Attention is called to the number of tonsillectomies and peritonsillar abscesses.

I am much concerned at present about the scientific results of this war in the medical line. Naturally, of course, I am interested first and chiefly in my own. My efforts must be largely confined to reminding the men in the hospitals that a great opportunity lies at their hand, and urging them to grasp it. In a great measure it is a matter of keeping adequate records. One hesitates to add more paper work than is already necessary in the Army. The initiative in this matter lies with the commanding officers of the base hospitals and the chiefs of the medical divisions. By means of the Army records, men can be traced for years to come. What better chance on a large scale has the medical profession ever had of settling the results of certain operative procedures—for example, tonsillectomy in chronic affections of the heart or of the joints—than is before it now? Practically every medical man serving in the Army wants to go abroad. I have been in France twice, but I can assure you that it is a great question in my mind whether there is not a fuller scientific opportunity in this country.

THE EQUIPMENT AT CANTONMENT BASE HOSPITALS: PERSONAL NOTES

The equipment at the cantonment hospitals is nearing completion. At the beginning of the war it was found that 80 per cent. of the surgical instruments were of German make. The instrument firms of this country were at once lined up and asked for maximum output. For a time the men who were first at the hospitals had but little to work with except the instruments which they brought with them or had sent from their offices. Now it is only a question of asking for reasonable things and knowing how to ask for them and to have a vigorous commanding officer back up the request and repeat it if necessary, in order to get all essential instruments. Naturally the whim of every operator for special instruments cannot be granted. It is still good policy, however, to carry one's pet instruments. Then one operates at ease from the start. If the instruments wear out, this can be called part of one's contribution to the cause in place of buying more Liberty Bonds.

Speaking of being first on the ground reminds me that in the beginning days some of the men did not see why they were required to be on the ground so early, why they were not left at home until things were further along. They were sent because their experience was needed to start things properly. In banks, clerks are not made directors. Of course in many cases the men first on the ground were uncomfortable. In the beginning some murmured a bit; now they brag of it. I have yet to talk with one of the pioneers who would have missed these beginning days. In many cases they made the hospital what it is at present even, like Day, taking part in the carpenter work. Where the men realized their job they saw to it that the head building was not pushed off the map, that it was not used for extra barracks, that it was well placed, that the original plan was even improved on. Take Holmes, for instance; he was put in charge of all the building by the commanding officer, and the result is no surprise to those that know him. The rest of the hospital had steam for its operating room. As a matter of course, Holmes soon had it for his building. He got not only steam but everything else that the Army allowed, and I suspect some things that were not allowed. In fact, he has one of the show places among the cantonment hospitals. He is an early bird if there ever was one, and always collects a large basket of worms wherever he goes. Pierce is happy at Grant now that he can keep his shoes and his clothes clean. Eagleton, at Dix, is still in a delirium of enthusiasm. Knowles has a fine place at Devens, and Skillern has developed a taste for administrative work and has aspirations to become a commanding officer. He also is much interested in his band. He has promised to embarrass me by meeting me with it when I next go there. Harris has gone to Oglethorpe to take charge of the teaching of otolaryngology. His worries have begun and mine have finished. Berens, Greene, Emerson and Fetterolf are just coming into the service. Wherever they go, the Surgeon-General's Office knows that things will run right. Levy got as far away as he could and is at Camp Lewis, American Lake, Washington. Wherever men of this stamp are placed there will be no more rumors of substandard work like Wild's incision for mastoiditis, and no suspicion of overoperating.

Haskins went early to West Point and is now professor of military hygiene. Friedberg is at Doniphan, and one of the men working under him says that being in the clinic there is better than any postgraduate course abroad.

During the year and since the entrance of this country into the war, Ingals has died. He took great pride in acting for the Surgeon-General's Office as state adviser, looking up the standing of applicants and furnishing the division of otolaryngology with their rating.

His figure comes back to me now as he stood last year by the dinner table after the banquet of the American Laryngological Society. He spoke about the war and said quietly but firmly, as was his custom, how he regretted that he could not take a more active part. He did his part, however, to the limit of his strength after the habit of his life. He suffered greatly, but lack of patriotism in a friend or acquaintance hurt him more than the pain of one of the cruelest diseases.

THE PROBLEMS OF THE SURGEON-GENERAL'S OFFICE

Naturally there have been many worrying problems for the Surgeon-General's Office to pass on. Of these, otolaryngology has had its share with the other departments. The first was the problem of consultants. Three or four consultants were appointed, but the plan from the start worked poorly and the medical officers who held such positions had to be given the choice of taking full time duty or going on the inactive list. Part time service is considered by the man who is giving full time as an unjust discrimination against him. He holds that all men have an equal right to it, and they have. Not only does it carry an unjust discrimination, but it destroys military uniformity and control. These, of course, are simply other names for discipline, and discipline is the backbone of the military machine.

The commanding office of an army hospital naturally has pride in having a staff of medical men who can cope with all the cases that come to his hospital, however difficult. If he is not so fortunate in his personnel or if unusual cases occur, he is at liberty to call in the most available civilian physicians. This has been necessary in at least one hospital and may be necessary again, unless more of the experienced otolaryngolgists of the country enter the service. There will be, of course, some men who cannot enter the service on account of physical disability, age, or some other sufficient and good reason. Let these men, if they want to be of use, make themselves known as standing ready to help as civilians; but they should be careful not to embarrass the government by trying to be both in uniform and out of it.

Service as contract surgeon has not been used in otolaryngology, although he has been employed in some of the other departments. Pressure is being continually brought to have the government use the civilian hospitals as a part of the war machinery. If I should give my own opinion in this matter, it would be that if the war is to continue three or four years more I can see how this may become necessary. At present, however, it brings up the old question of divided control and part time service. The Surgeon-General's Office, therefore, does not favor it.

The problem of the medical student has met a happier solution. Procuring a medical education is considered by Washington as preparation for the Medical Corps of the Army, and the medical student graduates by law into that corps. Those who are serving internships in hospitals have been allowed a year for such services. Naturally, however, many of the more ambitious and the most patriotic among our young men prefer to enter the Army at once and let the Army experience take the place of the internship.

As I look at it, it is axiomatic in a war of the magnitude of the present one that our hospitals are to be short handed, and that the medical schools must run on reduced personnel. Elaboration of courses must be eliminated for the time being and the schools come down to the three R's of medicine. Both hospitals and medical schools, however, can help themselves by doing away with the age limit and bringing back into service the men who have been retired. There is at present a committee in the Surgeon-General's Office which has this most important matter of teaching in the medical schools in charge for adjustment. There is every disposition to look on both sides of the question—England's mistake is well known. The Surgeon-General's Office has been fully reminded of it.

THE NEED FOR MEDICAL OFFICERS

I am continually asked if there is still need for medical men in the service. Sixteen thousand are now serving, but an imperative call has gone out for 5,000 more. In the general branches of the medical service, physicians of large hospital experience are badly needed. From all the cantonments the cry comes, Send us experienced men. Otolaryngology is better off than general medicine and surgery. However, when the base hospitals begin to go overseas in numbers there will not be enough experienced otolaryngologists to take their places. To make the department of otolaryngology what it ought to be, there should be on file, ready for instant use, the names of 200 otolaryngologists of ripe hospital experience. These men should be ready to take their physical examinations and send in their application papers on telegraphic notice. At present the available list is less than fifty. As things stand now, if your name was on such a list you might be used in six weeks or six months. However, by standing ready to apply for a commission, you have put yourself at the disposal of the government and have fulfilled your duty, at least as I see it.

If you take the combined membership of the American Otological Society, the American Laryngological Society, and the American Laryngological, Rhinological and Otological Association and omit the duplicate names and compute the percentage of the members who are in the service, it is found to be about 22 per cent. There are five lieutenant-colonels—Kopetsky and Imperatori in the field ambulance, Haskin, professor of military hygiene at West Point, and Richardson and Mosher in the Surgeon-General's Office. There are forty-one majors, twenty-six captains and eight lieutenants. The records also show that there are in active service 210 otolaryngologists and 232 ophthalmologists. Unfortunately, I do not have the figures for the special sections of the American Medical Association. Owing to the large size of these sections, I should imagine that the percentage would be somewhat less.

RETENTION IN A SPECIALTY

At the beginning of the war, the Surgeon-General, with his large grasp of affairs, made the statement that specialists would be used in their specialty as far as the exigencies of the military service permitted. No absolute promise could be made, and none was made. Naturally some men have tried to kill the goose that laid the golden egg by considering this statement a promise. This attitude has been especially true of the men just entering the specialty. No military organization could stand for a minute if so constructed. Full command is essential in order to meet changed conditions and emergencies. Up to lately the great majority of the specialists who came into the service have been used in their specialty. A few that have been found incompetent have been transferred to other lines of the medical service. I am aware also that a few men have escaped retention in their specialty, and these failures, I am also aware, will be talked about and made the most of to the end of the chapter. The fact remains, however, that never before in any war have the medical officers been assigned in accordance with their special training as they have in this war; and this is all due to the recognition of modern medicine by the present Surgeon-General.

Within the last month the shortage of medical officers has become so acute, the needs of the field service, without which the Army from the medical standpoint could not exist a day, have become so pressing that many of the medical men within the draft age, specially trained or not, have been released to field service. This, of course, is essentially a young man's job and one that appeals to the right kind of young men. This emergency has made it difficult now to retain in his specialty any man under 40. How long this shortage of men in the field service will last depends in a great measure on how the medical men of the country respond to the recent appeal. It was this scarcity of medical men that made the last call of the Council of National Defense necessary. War has always been an affair of young men, inconceivably sad, of course, but, in a just cause, most glorious. This war, from a medical standpoint, has been an affair of older men.

It goes without saying that not all physicians are equally well trained; that not all have had the same hospital advantages. As not all the physicians entered the service at the start and at the same time, it follows that those who came in first will rank, for a time at least, those who came in last. It cannot be made fair any other way. The men who gave up a year ago—and what they gave up in many cases was all that they had—are not to be lightly pushed aside by those who took a year to arrange, bargain and decide. There is no game in civil life in which such a thing would be called fair. Why should it be asked for in entering the Medical Corps of the Army?

There are not enough men of operating experience to make the medical service in otolaryngology what it should be. Some of the best men I know are not in the service—best in one sense. These men are beginning to come in. In the year that has elapsed they have been able to keep their homes open and be with their families; yet in spite of having delayed, and in spite of having enjoyed these advantages, some of them ask on entering the service that they supplant the men already in the field. Not even a German would call this fair.

I am often asked where the young medical men are, what the matter is with them that there are not enough to do the commonplace work that makes up so large a part of the army medical officer's day. If they were all the sons of physicians I should say that they took after some of their fathers.

THE CHARACTER OF THE MEDICAL WORK

The opinion is often expressed that the highly trained physician is wasting his time in the Army, that he would be doing more good staying at home attending to the civilian population. At times this view expresses an honest conviction; occasionally, alas, it is used to drug an awakening sense of duty. As I see it, there is an abundance of worthy opportunity for the man able to grasp it.

It is true, of course, that commonplace work predominates; that there is plenty of boy's work, as some have called it; that for the moment at certain places there is plenty of no work at all—to use a Hibernianism—plenty of just staying on the job waiting and prepared, which, by the way, is a new thing for us. It is true, to repeat, that there are plenty of all these nonpicturesque and nonstimulating things; yet those who are making up their decision to serve or not, if they let the question rest here, miss the most vital point of all. In the last analysis, no one enters the service to do special medical work, to increase one's scientific reputation or to gain one. The basic idea is to help win this war in the shortest possible time, or, as the boys say, "to lick the Germans;" and nothing which contributes to this end, however tedious and commonplace it may be, is beneath my dignity or, saving your grace, beneath yours.

It must be admitted that it is hard at times to hold true to this glorified view of the work, especially when one sees the inequality of sacrifice made by men even in the service, and when one learns that some of them are smugly adding to their substance even in war time and one knows that his own is lessening; but hold true to it one must. It is your guiding star in this lonely job of measuring up to your duty in your allotted place. If you think differently and stay out of the service when you should serve, you must be prepared some day to tell your daughter—it will not be necessary to tell her mother, for she will have it buried in her heart—that her girl chum's father, not her own father, kept the faith. It has made me heartsick and weary beyond words to sit at my desk in the Surgeon-General's Office and read and hear this and the other threadbare excuse which medical men give for not joining the Army Medical Corps. As I look at it after a year of trying to do my bit, those who make these excuses have lost their American heritage of red blood.

ABSTRACT OF DISCUSSION

Major Charles W. Richardson, Washington, D. C.: I would like to have heard from some civilian doctor on this subject. It is a half-stated subject when it is stated from the military side only. I played the game from the beginning. First, as chairman of the subsection of otolaryngology in the Council of National Defense, then as chief of the otolaryngologic section, division of surgery of the head, Surgeon-General's Office, during the absence of Lieutenant-Colonel Mosher on temporary duty in France, through legislative work, and later in the organization of the section of defects of hearing and speech in the division of physical reconstruction. As to the assignment of service: It is Colonel Mosher's desire to keep all the men in otolaryngology accepted for that service. It is to his interest to do so, and he feels obligated to do it for you; but that will be prevalent largely in the case of men over 40. But there are times, as you know, when the general service is pressed—I mean the field service. They have had two or three such pressures and they have had to take the younger men and put them in the field service. In going over the cards in the personnel division last winter, when I was in the division of surgery of the head, I found six men prominent in otolaryngology who were in field service. I took the liberty of writing them a personal letter, not from the office, but from my home, and asking if they would like to go back into otolaryngology and be assigned there. I was very much surprised to receive a letter from each and every one of them telling me that they were delighted with their regimental service; that they were learning more there than they thought they would ever be able to learn in medicine, and they were more than willing to stay where they were. That was interesting to me. So, remember one thing, that the exemptions for you in otolaryngology will be maintained if it is possible to do it. For younger men, under 35, the exemption cannot be made, because these men are the men who have not gotten so far into laryngology; they have not gotten so far away from general medicine or general surgery, and they can be spared for field service. Always remember that when you put in your application for service you have Colonel Mosher as your guardian in the office, and he will take care of you.

Capt. Robert H. Fowler, New York: At Camp Mills last summer we were "first on the ground" in more senses than one, for the officers slept in open tents that had no floors. One week after we arrived, the pegs were placed, the poles up, and we had a hospital going with 400 men under tentage. The "head specialists," including the eye surgeons, were given one small room, and, with the whole Rainbow Division in an open camp to look after, we soon found that there were more cases of nose, throat and ear trouble than we could handle. Chronic conditions had to be excluded, and those patients were given preference where treatment or operation promised to send soldiers quickly back into the line. Every tenth patient who reaches the hospital is referred to our section for treatment, and often there is need for ear and throat operations which, from the Army standpoint, are very much worth while; and which gain us the respect of the Regular Army officer in that they add strength to the fighting unit.

The chance to help an individual soldier "carry on" is frequently seen, and, in addition, it sometimes happens that there is opportunity to expedite matters for a whole unit in a pinch. At the Garden City Aviation Concentration Camp, in November, an epidemic of diphtheria threatened, as one or two cases had occurred. By making 300 cultures, and thus finding and isolating six "carriers," it was made possible for three squadrons to be moved to a distant assignment on schedule.

During the first two months of my assignment at the base hospital, Camp Shelby, in charge of the ear department, more than 100 cases of acute purulent mastoids were operated; thirty similar operations had been done during the two weeks preceding my arrival. This large number of acute mastoid infections in one camp during a space of three months was the more surprising in that there had been at the two other camps, where I had been stationed, during the preceding five months, only half a dozen cases altogether. The fact is that at Camp Shelby there was a streptococcus epidemic, following a measles epidemic, which had a specific tendency to attack such tissues as the mastoid cells. It has been suggested in one of the papers on "Contagion in Military Camps" that when an epidemic has assumed large proportions, the virulence of the organism becomes greater. Perhaps it is on this account that we found it imperative to act with the greatest promptness in these cases, since complicating mastoiditis followed more rapidly during this epidemic than in the sporadic type of mastoiditis seen ordinarily in civil life. Under the circumstances, we arranged to have the otitis cases reported early from the field hospitals and regimental infirmaries. Incision of the drum done promptly arrested the progress of a certain number of these cases, but in a surprisingly large proportion it was necessary to operate on the mastoid, and it is gratifying that nine out of ten of the soldiers who had the mastoid operation performed on them during the winter months at Camp Shelby, are already doing full duty. One point came out quite clearly, and my conviction on this is very firm, that the best results are obtained by immediate operation when there is evidence of acute purulent mastoiditis. Early operation is safe; danger lies in delay.

Dr. H. W. Loeb, St. Louis: This war has made a new era in surgery, in war surgery, especially in this country, so far as it has established the validity of ophthalmology, otology and rhinology as essential elements of the organization. Last year we left this to a committee, and this committee has done its work, with the help of the ophthalmologic committee; but I think it should be known that it is through the agency of Colonel Lyster, Colonel Parker, Colonel Mosher, Colonel Richardson, Colonel Black, Colonel de Schweinitz, Colonel Bordley, Colonel Greenwood and also Colonel Wood that this plan contemplated a year ago has been established, and I do not believe that the time will ever come again when the United States Army Medical Service will be carried on without these great and important specialties being given their proper place.

Capt. John B. Potts, Omaha: I had the pleasure of being associated with Captain Fowler for two months in Camp Shelby during the epidemic of mastoiditis which occurred at that time. When I went there—Captain Fowler preceded me by a month—I questioned whether it was necessary to do as many mastoid operations as were being done. Captain Fowler showed me his cases and we went over the histories. Previous to Captain Fowler's arrival they had attempted to wait two or three weeks for the ordinary mastoid to break down, or to decide whether it was absolutely necessary to operate, and their results had not been satisfactory. The percentage of cases that did badly was large—larger than it should have been; much larger than in civilian practice; larger than I have seen in epidemics. Captain Fowler was convinced that he was dealing with an epidemic different from anything he had encountered before, and which required more radical measures in the sense that he would have to operate sooner—less radical in the sense that he would get drainage sooner. The result was very striking. From the time he began operations early the basilar meningitis and other complications practically stopped. He did not operate in every case. He had recourse to the roentgen ray, blood count, bacterial count and consultation with an internist, surrounding himself with every safeguard before operating. In the fulminating cases, operation was performed at once. I think the early operation saved many lives. It was simple, because many of these cases followed pneumonia and some measles. Complications occurred less often. One patient developed an endocarditis as a complication after the operation. The mastoid healed nicely, and there were no complications, but about three weeks after the operation, when the mastoid wound was apparently healed, the temperature rose again, because of an acute endocarditis. This quieted down and the man's temperature was normal for two days, and we thought he was going to get well; then his temperature rose again, but it was of an entirely different character, showing that he was developing a meningitis, which caused his death. The necropsy gave evidence of extension from the mastoid. I believe the meningitis was secondary to the endocarditis. In a case of scarlet fever we delayed operation until about the seventh or eighth day. The mastoid complications appeared several days before the temperature from the scarlet fever dropped. A paracentesis was done immediately so that we had drainage. About the second or third day after the paracentesis his temperature began to rise again, as high as 102 and 103 F. He was a very sick man; he had a great amount of pain. When the mastoid was opened the bone was almost black and very necrotic. On the second day after his operation his symptoms cleared up and he made an uneventful recovery. With such a rapid destruction of the mastoid it seems to me we were taking a great chance waiting as long as we did.

POLLAKIURIA AS A FUNCTIONAL DISTURBANCE DUE TO EYESTRAIN

CAUSES OF EXCESSIVE FREQUENCY OF MICTURATION *

W. W. KAHN, M.D.
DETROIT

It is a remarkable fact that in such a well systematized science as medicine, so perfectly obvious a fact as micturition has escaped a clear-cut definition of its various phenomena. The looseness of the terminology has engendered looseness of diagnosis and therapy. We are, therefore, daily encountering essays in our medical literature dealing with incontinence of urine which mean principally excessive frequency of urination. I was as much a sinner as the rest, as may be seen by one of my previous articles,[1] in which I reported sixty-four cases of pollakiuria under the false title of polyuria.

DEFINING THE SUBJECT

The trouble lies in choosing one term to describe two widely different phenomena. In a medical dictionary[2] we find, for instance, anuria defined as (1) retention of urine and (2) suppression of urine. The first means mechanical retention of urine in the bladder or pelvis of the kidney, while the second means a suppression of excretion of urine. These phenomena are entirely different in causation, prognosis and treatment.

Oliguria is defined as an abnormally diminished discharge or secretion of urine — two widely different pathologic entities.

Incontinence of urine is defined as unconscious, involuntary dribbling of the urine, due to paralysis or inactivity of the sphincter vesicae or due to an overdistention of the bladder (incontinentia urinae paradoxa). This is a very good definition; however, many medical writers do not keep strictly to the meaning of the term, but include in their themes two other maladies, namely, the excessive frequency of micturition, or pollakiuria, and enuresis.

Enuresis has also two meanings, according to Foster's definitions: it may mean involuntary micturition, either diurnal or nocturnal, or it may mean incontinence of urine from all kinds of causes.

In order to bring clarity to my mind as to the symptomatology of micturition in relation to its frequency, but not the amount of urine, I classified it thus:

1. Anuria, absolute suppression of micturition.
2. Oliguria, abnormally diminished frequency of micturition.
3. Orthuria, normal frequency of urination.
4. Pollakiuria, excessive frequency of micturition.
5. Enuresis, diurnal or nocturnal involuntary discharge of urine.
6. Incontinentia urinae, constant and involuntary dribbling of the urine.

FREQUENCY OF MICTURITION

The only difficulty in this classification was to decide on the normal frequency of micturition. To find this norm of frequency I searched the textbooks on physiology in vain. I placed it, after numerous consultations with able general practitioners and urologists, at from three to five evacuations of the bladder during the waking hours. Any necessity of breaking one's sleep to void urine is pathologic, except when an abnormal amount of fluid has been taken before retiring. With from three to five evacuations of the bladder during the day as a norm, one evacuation a day would come under the head of oliguria, and six or more evacuations during the day, or those that wake a person from sleep to urinate, would come under the head of pollakiuria.

That the subject of disorders of micturition is very vital is proved by the great number of articles that have lately appeared in our medical journals.

One excellent article, written by Dr. H. G. Bugbee,[3] has a nearly correct title, namely, "Frequency of Urination in Women." What he meant was excessive frequency of urination in women. In this essay he has gathered statistically the causes of too frequent micturition in a thousand women and girls, and finds that increased frequency is one of the most common disorders of urination; in his tabulated findings he comes to the conclusion that all except thirty-four cases show some local lesion, not only in the bladder, but anywhere in the urinary tract. The thirty-four cases not showing any pathologic change whatsoever, he classifies under the head of neurosis.

NEUROSIS AND MICTURITION

In spite of the small number of neurotic cases found, Bugbee seems to feel the "stigma" of not having any pathologic lesions in these thirty-four patients, and the

following physicians who discussed his paper seemed to agree with him fully.

John R. Caulk of St. Louis[3] declares:

> This class of cases, seen frequently in young women who have been stamped as neurasthenics and hysterics, we must be careful about. Urologists who use the cystoscope do not make such mistakes very often, but it is the commonest mistake for the general practitioner to make. These patients almost always have gone for years as neurasthenics. I recognize that there is a neurotic bladder, but we have to be very careful in eliminating every factor before diagnosing a neurotic bladder, because so many of these cases are due to pathologic conditions at the vesical neck.

Theodore Baker of Pittsburgh[3] also was very suspicious about these thirty-four cases. He warns:

> We should look with extreme suspicion on the diagnosis of a neurosis; because we cannot find any pathologic lesion, I think we should be very careful about calling it a pure neurosis. I want to call attention to syphilis as a cause of urinary disturbance.

James A. Gardner of Buffalo[3] also coincides with Baker as to the probability of Bugbee's having overlooked organic lesions in the so-called neurosis cases. He says:

> Most of those cases are called neuroses because we are faulty in our diagnosis; we are not able to find out just where the trouble lies.

A. B. Cecil of Los Angeles[3] came the nearest to truth when he said:

> It is the so-called neuroses in which we are interested. The gross causes of frequency of urination we all recognize; but when we speak of "frequency" in women it brings to the urologist's mind that type of case in which we are absolutely unable to find anything the matter with the patient. We do not see this type of cases among men. It would seem that, perhaps, there may be in women a hypersensibility, where even normal urine under slight pressure will produce the desire to urinate.

If we take into consideration the limitations of our present medical knowledge and the inaccessibility of many lesions to our senses, it stands to reason that the thirty-four patients out of a thousand, in whom Dr. Bugbee failed to find any local lesions, probably had these, but they were not demonstrable by our present methods of diagnosis.

If, however, Bugbee and the others are right, as they evidently are, in demonstrating pathologic changes in the urinary organs of all cases of pollakiuria, is there any room or need for a neurosis theory, and if so, what lessons in practical therapy can be derive from it?

Foster[4] says:

> It is a matter of common experience that we feel the desire to make water sometimes when a large quantity and sometimes when a small quantity of urine has accumulated in the bladder. We have evidence that the bladder possesses to a very high degree that obscure continuous contraction which we speak of as "tone"; and, further, that the amount of its tone is exceedingly variable, the organ, quite independently of distinct efforts at micturition, being at one time contracted and at another flaccid and distended. When it is in a contracted state, a small quantity of fluid may exert the same effect on the vesical walls as a larger quantity when the bladder is flaccid. Hence, while the determining cause of the desire to make water is the pressure of the urine upon the vesical walls, the quantity needed to produce the necessary fulness is dependent on the amount of tonic contraction of the muscular fibers existing at the time. And we have evidence that this tone is regulated by the nervous system.

The truth of this statement was brought home to me accidentally by a case I first saw July 2, 1915.

REPORT OF CASE

Mrs. J. K., aged 28, the wife of a working man, was a neurotic patient, if ever there was one. On account of her many ailments, she was unable to do her housework and had to go back to her parents. She complained of headache and a sensation of pressure over her eyebrows and of pain in her eyes. She vomited when the headache was severe. She also suffered from photophobia and asthenopia for near and distance. Her appetite was variable and her digestion poor. She was constipated and exceedingly nervous. Almost daily she was given to prolonged spells of crying and screaming, especially when somewhat irritated. Her sleep was exceedingly poor, disturbed by terrifying dreams, recurring regularly when she tried to doze off in the morning. She felt more or less constant pain in the legs and in both inguinal regions. Her hands and feet were always cold, with frequent tremors and numbness of the hands, which also felt excessively dry. Her menses were never regular; menstruations recurred about every two months and were scanty and painful. Riding on a street car made her feel sick and miserable. At the time of her visit she weighed only 93 pounds.

The status of her nervous system can be guessed from the fact that when asked to step into the next room so that I might learn how far she could see, she fell on her mother's neck, tearfully kissing her, and kept crying, "Goodbye, mother! Goodbye, mother!"

Her vision was fairly good (20/20). As a refraction under a mild cycloplegic of homatropin and cocain was unsuccessful, I ordered the instillation of atropin. For reasons of refraction, the use of atropin was kept up three weeks. The examination revealed her need for the correction:

R. E. Cylinder plus 0.25 axis 60 Vision 20/16
L. E. Sphere plus 0.12 with cyl. plus 0.25 axis 180 Vision 20/10—

July 24, after three weeks' use of atropin, without glasses, she felt stronger, her feet felt hot, and her hands were warm and moist. She had no more headaches, but her head felt "big." There was no pain in the eyes, only soreness on pressure. Her appetite was ravenous. She could hardly get enough to eat. Her digestion was excellent. She had no more vomiting nor crying spells. She slept better and had no nightmare, but still had pain in the legs and slight attacks of pain in the groins. She asserted that she was gaining in weight.

It was on this date that she told me that, whereas she used to pass water every fifteen minutes during the day and five or six times during a night, she did not have to break her sleep any more, and that she urinated only two or three times during a day. Also, whereas her urine used to smell bad and show "brick dust deposit," it was now clear and odorless.

July 31, she reported that she slept excellently, and that her bowel movements were freer. Her menstruation was for the first time in her life painless and lasted nearly a week. She had no pain in the legs or groins, and her hands did not feel numb.

August 14, she reported no constipation, and she weighed 104 pounds, but complained of supra-orbital pain on the right side. She accepted for reading:

R. E. plus 1.50 with plus 0.25 axis, 60
L. E. plus 1.75 with plus 0.25 axis, 180

the lenses were to be worn in bifocal form. This was a case of premature presbyopia.

Oct. 5, 1916, she reported that she felt perfectly well in every respect. She weighed 117 pounds and had again taken up housekeeping. Her menses were more frequent and more normal in amount, occurring about every six or seven weeks, and lasting from four to five days. They were somewhat painful before the flow.

POLLAKIURIA AS A SYMPTOM OF EYESTRAIN

While this case is well worth reporting, on account of the patient's manifold symptoms and prompt recovery, the important point in connection with my thesis is the fact that her pollakiuria disappeared during atropinization. Naturally, I jumped to the conventional explanation that the absorption of the atropin diminished the secretion of the urine and thereby remedied the all too frequent micturition, when one of the coincidences so frequent in the practice of medicine happened the same day, July 24, 1915.

---

[4] Foster, Michael: Textbook of Physiology, Ed. 4, New York, the Macmillan Company, p. 549.

A working man, aged about 35, came in to report the results of his refraction. Among other things, he told me that he did not have to micturate so frequently as before.

I had determined his refraction about three months before that day, using no atropin, and instilling only a few drops of homatropin as a cycloplegic. As the small amount of homatropin could not explain the permanent improvement, the only conclusion possible was that the relief of the nervous system from the irritation caused by eyestrain must have somehow influenced the frequency of micturition.

I had never heard of pollakiuria as a symptom of eyestrain, so I began a vain search in the medical literature for a previous mention of this form of neurosis in connection with the eye.

The Index Medicus for the last sixteen years does not give any citations of literature on pollakiuria as a symptom of eyestrain. Neither do the accessible books on diseases of the nervous system mention it.

Oppenheim[5] speaks thus of the neurotic aspect of pollakiuria: "Pollakiuria (strangury with frequent evacuation of small quantities of urine [sic]) is occasionally observed." And then: "We often find abnormal irritability of the bladder due to neurasthenia, fear and abnormal introspection."

Of the textbooks on ophthalmology, not one mentions pollakiuria; neither does George M. Gould's[6] storehouse of eyestrain lore give any record of its occurrence. Only Stephenson[7] and Doyne[8] mention a case of true polyuria as probably caused by eyestrain, but no mention was made of pollakiuria.

After having my attention drawn to that neurosis, I began a systematic inquiry as to the frequency of micturition in all my refraction cases, with results as set forth in the accompanying table.

RESULTS OF REFRACTION ON POLLAKIURIA

	Number of Cases	Reported	Recovered or Improved	No improvement
Men	140	55	32	23
Women	176	71	53	18
	316	126	85 (65%)	41 (35%)

From July, 1915, to January, 1918, I determined the refraction in at least 1,500 new cases. Of these, 316 persons (140 men and 176 women), or about 20 per cent. of all cases, suffered from pollakiuria. For example, they urinated oftener than five or six times during the day, or had to get up from their beds to void urine, or both.

Of my 316 patients, 126 (55 men and 71 women) returned to report. Of these 126 cases, 85 (32 men and 53 women), or about 65 per cent., reported great improvement or recovery, while 41 (23 men and 18 women), or 35 per cent., were not improved at all in that particular symptom.

While the figures may seem startling, I do not attach much value to them. The number of cases is entirely too small to give us any valuable statistical figures. In an earlier essay[1] I had seventeen cases and reported seventeen cures, or 100 per cent. recoveries. They also depend greatly on the investigator's opinion as to what constitutes normal frequency of urination. But whether the percentages of recoveries are 65 or 25 or 20 or even 10 per cent. of the cases, the following conclusions stand out preeminently and are difficult to deny:

1. In my series of 316 cases, 140 patients were men. While their number was only slightly smaller than that of the women, the percentage of recoveries in women was twice as large as that of the men, a result very likely due to a greater nervous instability in the women.
2. The frequency of pollakiuria as a neurosis is immensely larger than we thought.

ORGANIC LESIONS AND NERVOUS IRRITABILITY

Bugbee and other urologists and gynecologists find some organic lesion in all, or nearly all, cases of pollakiuria. By experience they have learned that by treating the local lesions, they may bring the frequency of micturition back to normal. Although, in reply to a personal inquiry, Bugbee stated that he had no statistics ready on the results of the treatments, they must have been considerable or the profession would not unanimously connect this symptom with local lesions. These are facts not to be denied. On the other hand, we have here a series of some hundreds of cases of pollakiuria in which the patients were greatly benefited by refraction — a fact also not to be denied.

While I did not give a single one of my patients a physical examination, it is not likely that 100 per cent. of the eighty-five who improved, and of whom I have personal knowledge, had no local pathologic changes when an expert of Dr. Bugbee's caliber found less than 4 per cent. of all pollakiuria cases free from any visible lesions. So taking Dr. Bugbee's figures as correct, we must conclude that while nearly all the patients have some organic lesion, these lesions are only partial causes of the symptom, and that the general nervous system evidently has as much to do with it as the local abnormality has, if not more.

It is generally said that the practice of a specialty narrows the vision of the specialist, that in time every specialist comes to look at the entity of the body through the spectacles of his particular specialty, and that specialists claim they can cure the same diseases by the practice of their widely different methods.

Often the oculist, the proctologist, the gastrologist, the gynecologist and others pride themselves on having found and demonstrated the real cause of a certain malady and the cure of it by their own respective specialties.

It all sounds ridiculous enough, to be sure, but it is still more ludicrous to deny the claims of all these earnest and expert men. Their statements are absolutely true; they really cure their patients' ailments, and each one of us can bear witness to the truth of their contentions. How may this be explained? By what I have termed the phenomenon of multiple causation of symptoms. A symptom is only a local or general manifestation of more than one cause operating in the human body. The elimination of one or more of these causes makes the symptom disappear.

[8] Doyne, R. W.: Brit. Med. Jour., 1910, 2, 361.

In local manifestations, one of the dominant causes is always a local pathologic condition, while another is an irritated or weakened nervous system. As causes are different in values, a cure will mainly depend on the elimination of one or more of the dominant factors.

In my thesis on pollakiuria as a symptom of eyestrain there are at least two causes. One is the local pathologic change in one of the urinary organs, and the other is the hyperirritability of the nervous system caused by eyestrain. If the local lesion is dominant, no amount of correction of refraction will relieve the patient; only local treatment can do it. But when the local lesion is slight or negligible, the relief of the nervous system from the excess of nervous irritation will bring about a cure.

The disturbing cause in my series of cases was eyestrain, but that does not exclude malfunctions of other organs from having similar effects on the bladder.

CONCLUSIONS

1. Pollakiuria, or excessive frequency of micturition, must be strictly differentiated from polyuria and incontinence of urine.
2. In a great percentage of cases, pollakiuria is a neurosis, brought about by malfunction of a distant organ, especially the eye.
3. Contrary to the general medical opinion, pollakiuria is nearly as frequent in men as in women.
4. Before a surgical interference is tried, a careful refraction should be indicated in all cases of pollakiuria, except those in which it would have to be done for reasons other than the excessive frequency of urination.

ABSTRACT OF DISCUSSION

DR. ISAAC HARTSHORNE, New York: Dr. Kahn's differentiation of nomenclature is interesting and seems to be correct. In the first case cited, while evidently an eyestrain case, it would seem possible that the use of atropin for three weeks not only anesthetized accommodation but also reached the general circulation sufficiently to improve its tone together with some action on the smooth muscle fibers of the bladder wall. Dr. Kahn's relieved cases may be classified under functional disorder of the bladder from sympathetic irritation. At least three observers have reported cases of enuresis relieved by proper glasses.

The use of atropin by mouth not only produces cycloplegia but also diminishes the flow of urine by diminishing general glandular activity and by lessening the movements of the bladder wall.

Furthermore, if 1 per cent. atropin is used in the eye for cycloplegia, then approximately 1/120 grain of atropin is instilled into the eye with each drop, or about 1/60 grain in both eyes. Is it not probable that nearly as much of the drug is absorbed into the general circulation from the conjunctival sac as from the mouth and stomach, especially when the tear ducts are not held to prevent the passage of the drug to the nose? If this is so, then 1/60 grain three times a day becomes a faily large dose of atropin, and if continued after two or three days the alterations produced by large doses of atropin might well be expected. Atropin should not be used simply as a diagnostic test, but should be followed up by properly fitted glasses to reduce to a minimum the sympathetic reflex irritation. It is not the cycloplegia produced by atropin which tends to prove that eyestrain caused the bladder irritation, but the result obtained by correct lenses after the atropin has been stopped. It must be admitted that 65 per cent. of Dr. Kahn's cases were more or less permanently relieved; which doubtless would not have been the case had not proper glasses followed the use of one of the atropin group of drugs.

DR. W. W. KAHN, Detroit: I want to qualify Dr. Hartshorne's statement about the use of atropin. Some of the patients received homatropin. A few drops of homatropin would not affect the nervous system as much as atropin would.

As to my method, it simply takes eyestrain symptoms from the domain of uncertainties and guesses and puts it in the domain of certainties. It makes things clear to you and your patients. You know that so many patients get better and so many do not. Arguments which are not based on facts are useless.

DISCIFORM KERATITIS *

JOHN E. WEEKS, M.D.

NEW YORK

This form of keratitis, first fully described by Fuchs, is fairly well known to us all. It is not, however, a common disease, and is not so familiar to the greater number of ophthalmologists that a review of its characteristics will be without value.

Disciform keratitis is characterized by the appearance of a small approximately circular area of infiltration at or near the center of the cornea, accompanied by irregularity of the epithelium covering the infiltrated area, and partial or complete loss of sensation over that area. The infiltration slowly increases. From one to three complete or incomplete concentric zones or rings of denser infiltration appear at varying distances from the center of the patch. About one third of the cornea is usually involved, but a smaller or a much larger area may be included. From one to three weeks after the infiltration begins, one, and sometimes two or three, small yellowish white spots develop in the substantia propria at or near the center of the infiltrated area, located sometimes near the surface of the cornea, sometimes deep in corneal tissues. In many of the cases, fine, fairly straight, grayish white lines are observed, usually radiating from the center of the infiltrated area. These, according to Fuchs, are due to a wrinkling of Descemet's membrane.

The affection continues to progress for a period of from two to four months, and then gradually subsides with a permanent and not very dense corneal opacity throughout the infiltrated area. A quiet condition is reached in from three to eight months after the onset.

The symptoms are not severe unless distressing complications arise. They consist of increased lacrimation, very little pain, photophobia of a mild character, and dimness of vision, the degree of which depends on the density and location of the infiltrated area. There is also some pericorneal injection.

The complications are anterior uveitis; iritis, which may be mild or severe; and increase in tension, which may be very slight, lasting but a day or two, or may be intense, amounting to a severe secondary glaucoma, necessitating operative measures for relief. Corneal ulceration seldom develops; when it does, it is of a superficial character. The etiology is unknown.

Until recently the usual treatment has been of little avail. Cleansing the eye with boric acid solution often enough to keep it free from the slight secretion, and using mild antiseptics, together with measures to prevent the formation of posterior synechiae and to control the symptoms arising from complications, are the only measures that appear to be of value locally. In addition, the general condition of the patient is made as good as possible.

---

* Read before the Section on Ophthalmology at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

The prognosis is good so far as the integrity of the eye is concerned, provided destruction does not occur because of complications.

The following is a report of three cases I have observed.

REPORT OF CASES

CASE 1.—A. W. S., a man, aged 33, was referred to me by Dr. Henry W. Wandless. The patient had been under treatment by various ophthalmologists for an affection of the right eye for six weeks. A typical condition of disciform keratitis of a mild type was present, namely, a central whitish, opaque spot measuring about 5 mm. in diameter, and irregular in shape. It was situated in the substantia propria about one third of the thickness of the cornea below the anterior surface. It was surrounded by an approximately circular area of infiltrated cornea, consisting of alternating concentric zones of lesser and greater degrees of infiltration, the zones of greater infiltration being narrower than those of lesser infiltration. The zones or rings were not perfectly regular, but varied in thickness; nor was the infiltration of equal density throughout the zones. The epithelium over the infiltrated area was stippled, or slightly roughened, and at the center appeared depressed, on account of the loss of a part of the epithelial layer. There were a few narrow grayish lines radiating from the center of the area apparently at or near the posterior surface of the cornea. There was little irritation, slightly increased lacrimation and some photophobia. There was no pain of moment. The sensitiveness of the cornea was reduced over the affected area. There was a slight pericorneal injection below. The iris was a trifle less mobile than its fellow, but no evidence of exudation in the interior of the eye appeared. The tension was normal. The patient's general health was very good. The urine showed a slight excess of indican, but was otherwise normal. The Wassermann reaction was negative. There was no physical evidence of tuberculosis.

I made a diagnosis of disciform keratitis probably due to external infection, and was of the opinion that recovery would ensue in from six weeks to three months, leaving a pronounced thin opacity.

In regard to the treatment, I advised that a moderate dilatation of the iris be maintained so long as the process appeared to have any activity, provided an increase of tension did not develop. I also advised the bathing of the eye with a hot solution of boric acid twenty minutes three times daily and the introduction of an ointment of mercuric chlorid, 1:5,000, after each bathing. Meanwhile, the system was to be kept in the best possible condition. I advised the wearing of tinted glasses, if photophobia was annoying.

The symptoms of activity in this case gradually subsided, and the healing was complete in about five months from the onset of the affection. The patient's vision is now approximately one-half the normal.

CASE 2.—Mrs. A. L., aged 39, first noticed a slight blurring of the vision of the right eye, Sept. 7, 1917. There was no pain. September 11, the patient consulted Dr. John M. Wheeler,[1] who immediately admitted her to the New York Eye and Ear Infirmary. I was called in consultation, September 12. Dr. Wheeler had observed a faint infiltration of the cornea, had advised the patient to rest in bed, and had ordered the eye bathed one-half hour at a time with a hot solution of boric acid, and the instillation of atropin, 1 per cent., sufficiently often to keep the pupil dilated. September 12, there was a faint, almost circular uniform area of infiltration about 2 mm. in diameter over part of the pupillary area, slightly to the inner side and below the center of the cornea. It was a little more dense at the center than at the periphery. The epithelium over this area was very slightly roughened, that is, stippled. There was no pain. The iris reacted normally. The interior was normal. The vision was $^{20}/_{30}$ +. The vessels of the ocular conjunctive were slightly increased in size and number. The patient's general condition was apparently excellent. The urine, the blood count and the Wassermann reaction were all negative. There was no history of trauma. Although at this stage there was no central distinctive spot and no concentric ring of denser infiltration, a diagnosis of corneal infiltration, probably disciform keratitis in its earliest stage, was made.

Examination with high magnification showed defects in the surface epithelium over the area corresponding to the infiltration. The infiltration consisted of minute isolated deposits apparently situated in the substantia propria immediately beneath Bowman's membrane, extending into only a few of the lamellae, being denser and deeper at the center and growing gradually less toward the periphery of the infiltrated area. The infiltration had the appearance of an aggregation of irregular granules. There was no distinctive central depression or opening which might have been regarded as the point of entrance of an infected foreign body. The cornea was less sensitive over the affected area. Other parts of the cornea, the conjunctiva, the lids, etc., were of normal sensitiveness.

In addition to the treatment advised by Dr. Wheeler, a mercurial was given internally and an ointment of mercuric chlorid and petrolatum, 1:5,000, was introduced into the eye after each bathing.

The granular infiltration apparently ceased to develop for forty-eight hours. Then there was an increase, which continued until a fully developed disciform keratitis was present about two weeks later.

September 15, a slight increase in tension was noticed when the atropin was discontinued. As the slight increase of tension persisted, September 16, pilocarpin, 1 per cent., was instilled twice daily. The anterior chamber was of moderate depth. The tension subsided in two or three days, and the pilocarpin was discontinued. The infiltration increased slowly but steadily. September 24, two partly formed concentric rings or zones of denser infiltration had formed; the limits of the infiltrated area were ill defined. There was no central opaque points or spot, nor was there any pain. The ocular conjunctiva was slightly congested. About September 26, Dr. May saw the patient and advised the use of a 10 per cent. solution of ethyl-morphin hydrochlorid (dionin) once daily. After the first instillation, the tension became high and the cornea steamy, and the patient suffered an attack of acute glaucoma, which lasted two to three days, but was controlled by use of physostigmin (eserin) and pilocarpin. The anterior chamber was deep. October 3, the iris was involved in a mild plastic iritis, with the formation of some posterior synechiae, particularly at the lower pupillary margin. There was no pain, the tension was normal, and the anterior chamber was considerably deeper than normal. The iris now took on a greenish hue. The aqueous was not appreciably turbid. There was a very small, central, deep-seated, yellowish white spot. In addition to general tonic treatment, mercury by inunction was advised, and the desirability of using tuberculin was considered and recommended. About October 22, Dr. May, who was in charge of the case, gave tuberculin T. O., 1 mg. hypodermically, and repeated the dose four or five days later, increasing the quantity. There was a mild local reaction, evidenced by increased flushing of the ocular conjunctiva after each injection, and a very slight general reaction after the last.

October 30, I saw the patient in consultation with Drs. May and Reese. There was then a decided involvement of the anterior portion of the uveal tract. The anterior chamber was deep. The pupil was irregular, because of posterior synechiae. Atropin had been withheld because of the history of increased tension, but it was now used vigorously without causing any increase in tension. Ethyl-morphin hydrochlorid had again been employed without causing any appreciable change in tension. It was suggested that tuberculin in therapeutic dose be given every four or five days, and that mercurial inunctions be continued and given regularly, precautions against ptyalism being taken. The vision was $^{6}/_{200}$. The grayish white spot in the corneal tissue was about 1 mm. in diameter. This general line of treatment was continued. The patient was again seen in consultation with

---

[1] In the absence of Dr. C. H. May from the city this patient first came under the care of Dr. John M. Wheeler for the treatment of this affection. Dr. Wheeler called me in consultation and I was privileged to see the case frequently at first, less frequently later up to November 27. By the courtesy of Dr. May, who has furnished me with subsequent data, I am enabled to report the case.

Drs. May and Reese, November 27. At this time it was very evident that a decided change for the better had taken place. The pericorneal injection had largely disappeared. The anterior chamber was not as deep as before. The iris was more nearly of a normal hue. The vision was improving. The central grayish white spot was smaller and less dense. The treatment consisted of tuberculin administered hypodermically. Mercurial inunctions and general tonic measures were administered systematically, also atropin, and ethyl-morphin hydrochlorid. The patient steadily continued to improve. About January 20, she was virtually well. There still remains a thin opacity of the cornea throughout almost the entire area of the infiltration. The central white spot is scarcely more dense than the surrounding opacity. There are still a few small synechiae showing little, if at all, when the pupil is contracted. The vision equals 20/50.

A peculiar feature of the case is the almost entire absence of pain. The use of tuberculin and mercury appear to have been beneficial.

Case 3.—Mr. D. F., aged 18, was brought to my office by Dr. A. J. Greenberger, Nov. 22, 1917. November 12, the patient observed that the left eye was watering and that his vision through it was poorer than through the right eye. He thought he had pink eye. There was no pain. He consulted an ophthalmologist, who made a diagnosis of erosion of the cornea.

When I saw him, there was an irregularly circular infiltration of the left cornea, slightly above and to the nasal side of the center of the cornea, as well as a few spots of infiltration extending downward and toward the nasal side. The epithelium was roughened over the circular area, and a circular zone of denser infiltration was disposed just inside the border of the circular patch of infiltration. The anterior chamber was deep and the tension normal. The cornea was sensitive over the infiltrated area. The iris reacted readily. The vision was 3/200.

In addition to general tonic treatment, red mercuric iodid, 1/30 grain, three times a day, was prescribed. Locally, bathing the eye with a hot solution of boric acid and sodium borate, the instillation of atropin, 0.5 per cent. solution, often enough to keep the pupil moderately dilated, and the introduction of an ointment of mercuric chlorid and petrolatum, 1:5,000, in small quantity, into the eye after each bathing.

December 3, there had been but little change. In addition to the foregoing I advised a diagnostic dose of tuberculin T. O., 1 mg., to be repeated four days later in a dose of 1.5 mg., if no reaction was observed after the first dose. The tuberculin was given, resulting in a mild general reaction and a slight increase in the flushing of the ocular conjunctiva of the affected eye.

December 13, the iris was slightly congested. The cornea was about the same, except that a very small yellowish white spot had become apparent near the lower inner part of the irregularly circular patch of infiltration, situated about half way between the anterior and posterior surfaces of the cornea. A faint inner zone of denser infiltration was beginning to appear. The ocular conjunctiva was slightly congested, and two small vessels extended from the margin of the cornea into the infiltrated area.

December 20, the area of infiltration was larger. The iris was widely dilated. The tension was normal. The vascularity of the cornea was slightly greater. I continued the use of tuberculin B. E. in doses of 1/500 mg., injected every four or five days. The other features of the treatment remained the same.

December 31, there was a marked improvement.

Jan. 24, 1918, the eye continued to improve, vision being 20/100.

February 7, the infiltration was less. Only one small vessel ran from the conjunctiva to the spot of infiltration. The patient suffered no inconvenience.

The treatment now consists of tuberculin B. E., 1/500 mg., every four days, red mercuric iodid, 1/30 grain three times a day, and a nutritious diet. Locally the eye is cleansed with boric acid solution twice daily, an ointment of mercuric chlorid and petrolatum, 1:5,000, twice a day is applied, and atropin, 0.5 per cent. solution, is occasionally administered to provide against the possible formation of posterior synechiae.

February 28, the eye was quiet. A whitish, partly opaque patch occupied the site of the infiltration. The epithelium was intact and smooth. The vision was 20/50. Local treatment was discontinued. I advised that the use of tuberculin be continued four weeks longer.

OPINIONS FROM MEDICAL LITERATURE

Under the name of abscessus siccus corneae, Arlt of Vienna described this affection of the cornea as early as 1870, according to Fuchs, and taught the peculiarities of disciform keratitis to his students. Vossius[2] gives a very good description of disciform keratitis, but mentions it as an abortive interstitial keratitis. Grünert[3] reports seven cases, accepting Vossius' views of its proper classification. Fuchs[4] reviews the literature up to 1901, and reports on twenty-eight cases. In the seventh edition of his textbook, p. 189, he had described this affection as abscessus siccus corneae, after the teaching of Arlt, employing the designation "disciform keratitis" in 1901. Fuchs has observed disciform keratitis only as a monocular affection. Zani[5] reports three cases. In one case there is a history of a patient's having rubbed his eyes with hands contaminated with secretions from vaccine pustules.

Peters[6] reports a number of cases. He attributes the affection to a necrobiosis of the tissues, the true nature of which is not fully understood, resulting probably from disturbed innervation; and consequently he attributes the affection to impairment of nutrition. Injury to the endothelial layer induced by the edema resulting from trauma is responsible for the opacity. Infection or an abscess is responsible for the disk only in exceptional cases. Hadano,[7] working in Peters' clinic, examined tissues scooped from the center of the affected area in a case of disciform keratitis. He is of the opinion that he has confirmed Peters' contention, declaring, "A study of the tissue removed revealed no signs of inflammatory infiltration — only a few nuclei were found in the periphery and none in the central portion." No micro-organisms were found. Meller's[8] observations were based on the histologic examination of an eye which presented clinically the appearance of parenchymatous keratitis with a disk-like opacity in the deeper layer of the corneae. Secondary glaucoma developed as a result of a complicating uveitis. A shallow corneal ulcer had formed at the center of the cornea, and the globe was enucleated.

Findings.—The center of the cornea was the seat of an infiltrated area which included the substantia propria from Bowman's to Descemet's membrane. The epithelium was infiltrated with free, small, round cells, and was reduced to several layers at the center of the cornea. Bowman's membrane was normal. Descemet's membrane was thrown into numerous folds. Closely adherent to Descemet's membrane posteriorly was a thick exudation of fibrin which had the form of a disk. Meller summarizes as follows:

> "1. It consists of a well circumscribed disease focus, which undoubtedly is produced by an infection. The remainder of the cornea is healthy, with the exception of slight secondary changes.

> "2. The condition consists of an inflammatory infiltration, which proceeds from a point of infection in the surface, uniformly in all directions into the surrounding parenchyma, and also into the depth of the cornea, and produces a disk-shaped lesion with more strongly saturated edges.
>
> "3. This tendency to spread soon disappears, and a total necrosis of the infiltrate appears, which affects probably the cause of the process as well. Bacteriologic examination both intra vitam and in the sections was negative. This necrosis affects first the infiltrate, while the corneal lamellae remain intact, except where they are destroyed by the infiltration. The subsequent long-continuing inflammatory condition of the eye is the reaction of the healthy tissue against the dead tissue in the corneal parenchyma, a process of sequestration which in the avascular cornea is necessarily slow. The ultimate prognosis as to vision is poor because the tissue is infiltrated from the margin by cells, which finally produce scar tissue, and remain as a permanent opacity."

He believes that keratitis punctata superficialis is produced by the same pathologic changes.

Posey[9] reports two cases. In one case both eyes were involved. Veasey[10] reports one case. Zentmayer[11] reports three cases, one of which followed a variolus ulcer and one, herpes corneae. Landman[12] reports two cases, both of which followed doubtful injuries. There was no irritation in the one, and slight irritation in the other. He regards the condition as one of inflammatory infiltration. Monthus[13] describes two cases, one of which was bilateral, coming on after articular rheumatism, with cardiac lesions, in a patient with inherited syphilis. Under the title "Disciform and Postvaccinal Keratitis," Schirmer[14] reports seven cases resembling Fuchs' disciform keratitis, some of which were apparently due to infection with vaccine virus. He experimented with rabbits and apparently convinced himself that disciform keratitis in the human being is the result of infection with this virus. Erdmann[15] observed three cases. Each had increased tension at some period of the disease, a symptom that he thinks is often overlooked. He regards the disease as a neuropathic affection, and believes that the tissue necrosis is not due to an unknown bacterium, as suggested by Fuchs, but rather to disturbed innervation — the view already advanced by Peters. E. V. L. Brown[16] reports two cases, one in a boy with the stigmata of inherited syphilis. There were extensive posterior synechiae.

RESULTS OF OBSERVATIONS

In the seventy-two cases observed and collated, the youngest patient was 11 and the oldest 62 years of age. Disciform keratitis is a rare disease and with few exceptions is monocular.

Its period of activity varies from six weeks to five months. It may run a very mild course, or it may be accompanied by complications that may necessitate removal of the eyeball.

The etiology is not proved. The history of the cases and the changes observable at the onset of the affection make it evident that the first departure from the normal condition takes place in the very superficial parts of the cornea, such as the epithelium and outer lamellae, thus strongly supporting Fuchs' contention that the process is due to external infection. The clinical picture is so different from that following other forms of tissue necrosis due to disturbances of innervation and consequent impairment of nutrition, and the histologic findings (Meller and Hadano) so indicative of local irritation, that the theory of Peters apparently cannot be accepted. The symptom that seems to support Peters' views is that of loss of sensibility, which occurs in many but not in all of the cases. The nature of this infection is yet to be determined.

Schirmer's suggestion, based on his experiments with vaccine virus does not carry conviction. None of us who has seen infection of human eyes with vaccine virus has observed a condition resembling disciform keratitis. Infection of the eye with vaccine virus usually involves the eyelids. It has been my fortune to see also involvement of the cornea in two cases. The infiltration was not accompanied by the formation of definite concentric rings of denser infiltration, nor was there a development of the usual whitish yellow spot or spots. In these cases the infiltration disappeared, leaving almost no trace, the process clearing up within three weeks. The behavior of the patients treated with tuberculin, as reported in the foregoing, together with the clinical manifestations of the disease, strongly suggests a tuberculous process, in spite of the fact that the histologic examination (Meller and Hadano) failed to disclose microorganisms.

While in other respects the affection does not present the ordinary clinical picture of tuberculosis of the cornea, the appearance of the yellowish white spot, after the disease has existed from ten days to three or four weeks, closely resembles the yellowish white foci observed in tuberculous keratitis. The apparent local reaction to diagnostic doses of tuberculin and the apparently favorable results from therapeutic doses of tuberculin are very suggestive of a tuberculous process. The effect of tuberculin in two cases is, of course, not enough to establish etiology, but it is enough to encourage the further use of tuberculin in these cases and the further observation of such cases with a possible tuberculous origin in view.

ABSTRACT OF DISCUSSION

Dr. William Zentmayer, Philadelphia: Disciform keratitis is a rare one, although it probably occurs with greater frequency than the literature would indicate. The number of reporters, most of them having observed several cases, is small, indicating that the disease is not generally recognized. It is, I believe, sometimes diagnosed wrongly, the presence of a disciform nebule, but lacking other features of the true affection, leading to the error. Knowing this mistake to have been made, I said in reporting a case of disciform keratitis some years ago, that the term, emphasizing as it does only one feature of the disease, led to the inclusion of corneal opacities presenting an annular form.

As Dr. Weeks points out, and as supported by one of his cases, anesthesia of the cornea over the affected area is not a constant feature. It has been present in only one half of the cases I have seen. The disk is often eccentrically located in the cornea. Occasionally, there is a development of superficial vessels at the limbus corresponding to the nearest approach of the disk to the corneal margin. I agree with Dr. Weeks that the etiology is unknown, and I am not willing to accept a neuropathic origin. Wagner reports a case occurring in a man 77 years of age. His conclusions are that disciform keratitis is characterized by a disklike part of strongly altered corneal tissue, lying deep; that it is caused by toxins produced by undiscovered micro-organisms existing in the epithelium. The finding of giant cells in the exudate in the anterior chamber of an inoculated animal is significant.

The differential diagnosis of disciform keratitis is of great interest and importance. The causes of this condition are numerous. Should we accept a tuberculous origin for this affection, could it not be explained in the same way as the cases of interstitial keratitis which we see develop in patients with inherited syphilis as the result of a trauma?

Dr. John Green, Jr., St. Louis: Keratitis disciformis has generally been regarded as a self-limited disease, practically uninfluenced by any form of treatment and terminating in more or less opacity, due to the formation of scar tissue. Posey, who in 1904 recorded the first American case, remarks that "therapeusis is unavailing." This view is shared by most textbook writers, who content themselves with offering such therapeutic suggestions as would presumably be of benefit in any chronic corneal inflammation.

In a case I reported in 1913 prompt improvement and a rapid cure followed repeated subconjunctival injections of a 2 per cent. saline solution, after the failure of classical methods.

Dr. Arthur G. Bennett, Buffalo: I have seen three cases of this type. The treatment that I applied to two of these cases was very satisfactory, after I had tried all the classical methods for five or six weeks without getting any improvement. Under cocain anesthesia, I flooded the eye with fluorescein, opened up the area of infiltration with a knife and then with a sliver of wood I cauterized the necrotic area thoroughly with phenol. I discharged that patient cured in a week.

A young man, who had been in the care of a very competent oculist in another city for three months, was sent to me with a diagnosis of tuberculosis. I employed the treatment mentioned at once, and with the same good result. The necrotic area is stained with fluorescein immediately you open into it so that the exact limits of this area are delineated. Cauterizing that area with phenol destroys absolutely every part of the infiltration. I was gratified at having a perfect recovery within a week; and that man was accepted in the Officers' Reserve Corps within a month, and is now serving with the Army.

Dr. Will Walter, Chicago: Improvement following the administration of tuberculin is not more than suggestive evidence of tuberculous infection. Observations are being made with increased frequency that antibody forming vaccines and neutralizing serums are more or less interactive. Antityphoid vaccine has occasionally cleared up staphylococcus infections, and antitoxic streptococcus serums have improved conditions due to other infections. Tuberculin often raises the white cell blood count. Sahli made this a diagnostic point in mild tuberculosis. I have employed staphylococcus vaccines in recurrent furunculosis, and with good effect, although often without raising the white cell count. In the few cases of ulcers of this type which I have observed and treated it has been used with this thought in mind and not with the idea that it was a tuberculous lesion, although it may be. The same therapy is employed as a routine in all forms of corneal ulcer whenever the white cell count is low.

It has always been used with measures which promote local resistance. Prominent among these are the high frequency current, with vacuum tubes, through the closed lids, and later the sinusoidal current; and last but not least heat, not as usually applied, but by the sanatorium method, which gives you a much greater degree of heat than by direct methods, and not persistently applied, but at intervals of two or three hours. The sinusoidal current is of value in this condition because its waves prevent scarring and stimulate the nerves to normal function. The results from this technic will surprise those who have not tried it. It certainly is very effective in shortening the duration of this disease, for my patients have not had the long period of suffering which the records tell us must be expected.

Dr. Edgar S. Thomson, New York: I have seen two cases of disciform keratitis—the first I have ever seen. I do not see how there can be any other cause for the condition other than a low grade infection. The whole appearance and characteristics of the condition are infective.

I treated a young man, otherwise in perfectly good health, for six weeks without the slightest benefit, when it occurred to me to destroy the infective material as Dr. Bennett described. I applied Shahan's thermaphore in this case, heated to 160 F., directly over the disciform spot, for one minute. He made a very rapid recovery. The eye began to whiten at once, the hypopyon absorbed, and he was out of the hospital in a week, the whole case having lasted a little over two months.

Another case was seen in consultation, and I did not have a chance to apply that treatment; but we have had very good success with the thermaphore in other cases of similar character.

Dr. F. Park Lewis, Buffalo: I agree with Dr. Bennett that disciform keratitis is much more common than we realize. There are two reasons why it has not been recognized; first, because attention has not been called to it as definitely as it should have been, so that it escapes observation; and second, because in all probability it is endogenous rather than exogenous in its infection. Dr. Blaauw reported a case before the Ophthalmic Club of Buffalo. It had the typical characteristics which have been outlined. The patient was a strong, rugged, well nourished man, who gave no other evidence of illness. However, his mouth was as insanitary as one could imagine it to be. There were evidences of pyorrhea and root abscesses. Great improvement followed the extraction of the infected teeth and the treatment of the pyorrhea.

I believe in the use of protein toxins. Dr. H. Gideon Wells, who is now working on the subject of protein toxins, told me that Dr. Kessler has for the first time succeeded in isolating a sufficient quantity of the histidins to make experimentation practicable.

They have reached the conclusion that all proteins give off very easily absorbable toxins, which produce a wide range of symptoms. When a case of disciform keratitis occurs, it is of great importance to search for a focal nidus of infection.

Dr. John M. Wheeler, New York: Two things impressed me very definitely in Dr. Weeks' case, which I saw first. There was an entire absence of symptoms, except for impairment of vision. Two days before I saw her this patient noticed that she did not see well with her right eye. There were absolutely no other symptoms. There was no pain or discomfort or photophobia to indicate that there was anything wrong with the eye. The eye was treated with atropin and hot baths, and in the first few days was apparently absolutely quiet, except for this round area of infiltration. Ethylmorphin hydrochlorid was suggested, and on the fourth day a drop of a 2 per cent. solution was instilled into the eye. The eye had been absolutely quiet up to this time. Within a few hours after the instillation there was an attack of acute glaucoma. It is impossible for me to dissociate the use of the drug in this case from the acute glaucoma.

Dr. Rudolph H. von Kotsch, Chicago: A few weeks ago a patient came to me who had been treated for two months by another doctor. He did not improve and became dissatisfied. Some friends suggested the use of argyrol; so he used that for four weeks, but the eye continued to grow worse. Then he was referred to me. I used the actual cautery, but very lightly. The following day the eye showed improvement. In about two weeks it cleared up entirely, and vision is now almost normal.

Dr. Jesse S. Wyler, Cincinnati: Is it not possible that some of the men who have discussed this paper have confused true keratitis disciformis with deep corneal abscess and centralized interstitial keratitis? I have seen only two cases of disciform keratitis in the European clinics, and as I remember them, there was no stippling of the cornea above the lesion. There were no synechiae and no hypopyon. I also agree with Dr. Walter in the action of tuberculin, considering it merely a means of increasing leukocytosis according to the paraspecific theory advocated by Darier.

Dr. John E. Weeks, New York: This is a microbic infection. The forms of treatment that have been successful in these cases point to the destruction of a causative agent, apparently a micro-organism. In regard to the possible endogenous nature of the infection, I do not think that theory is sound. In the cases which I have observed the disturbance is primarily a superficial one, never a deeply seated one, which it would be if it were metastatic. Secondly, it is advisable to give patients with disciform keratitis diagnostic tuberculin injections and see if a local reaction is produced. The result will aid us to determine whether this affection is or is not due to infection with tubercle bacilli. Hypopyon and deep ulceration are extremely uncommon, and when they occur must be due to added infection by some other micro-organism.

THE EFFECT ON THE KIDNEY OF URETEROVESICAL ANASTOMOSIS

EXPERIMENTAL AND CLINICAL REPORT *

ANDERS PETERSON, M.D.
ROCHESTER, MINN.

Baker, in 1878, reported a successful implantation of the left ureter into the bladder by operation through the vagina, for the relief of incontinence due to the opening of the ureter into the anterior wall of the vagina. In 1889, McArthur reported a similar case, in which he operated successfully. Davenport, in 1890, implanted an anomalous ureter by the vaginal route, with good results. In 1894, Bazy reported two instances of ureterovaginal fistula. One patient had an infected hydronephrosis which improved after the implantation of the ureter. Bazy tied a small catheter into the implanted ureter and suggested the use of pelvic lavage with silver nitrate solution, 1:500 to 1:100, for infection of the kidney. He also mentions two cases of ureterovesical implantation performed by Novaro in 1892. Franz, in 1907, published a report of nine experiments on dogs, with excellent results following ureterovesical implantation; also seventeen clinical cases in which four patients were cystoscoped, and the implanted ureter functioned normally. Krönig, in the same year (1907), reported the cases of nine patients operated on for ureteral fistula, following hysterectomy for cancer. His assistant, Dr. Rauscher, cystoscoped these patients from five months to one and one-fourth years after the implantation. Good function of the kidney was found in five cases; two showed stenosis and slight hydronephrosis. In two cases of bilateral implantation there was hydronephrosis on the left side and good function on the right side in one, and normal function on both sides in the other.

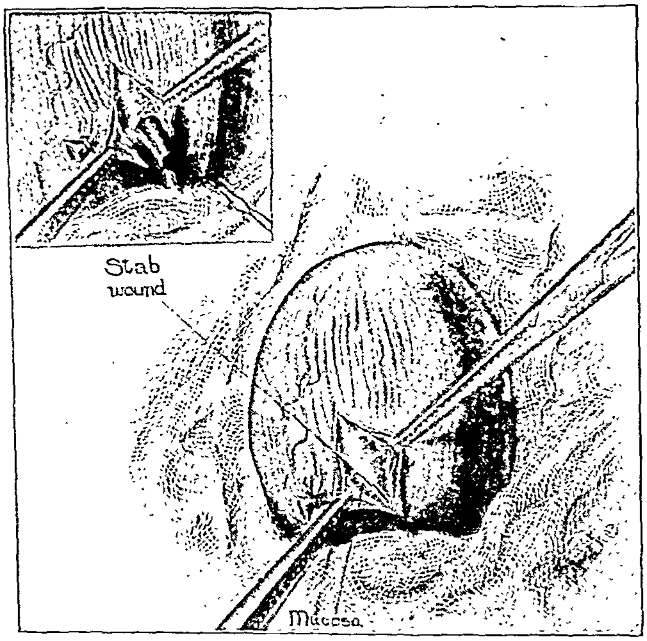

Fig. 1.—Coffey technic employed for implanting the ureter into the bladder; serous and muscular coat split and undermined for embedding of the ureter; (inset) split ureter pulled within the cavity of the bladder through the stab wound in the lower angle of the incision.

TYPES OF TECHNIC

Coffey, in 1911, published a technic for implanting the ureter or the common duct into the intestine. This consists of splitting the serous and muscular coats for three fourths of an inch and entering the lumen of the bowel through a small stab wound in the mucosa. The ureter is pulled well into the lumen by means of an anchoring suture placed through the split end of the ureter, and tied three fourths of an inch below its entrance. The serous and muscular layers are then approximated around the ureter, and one stay suture is placed one-fourth inch above the site of the anastomosis (Figs. 1 and 2).

Stiles' technic consists of entering the lumen of the bowel through a stab wound, and approximating the intestinal wall, without further dissection over the ureter. The wall of the ureter is also caught in these sutures. He omits the splitting of the ureter on one side, as well as the stay suture. These methods have been used with slight modifications in our work for implantation into the bladder (Figs. 3 and 4).

Furniss has recently published a simple method of ureterovesical anastomosis, consisting of the penetration of a double fold of the bladder wall with an artery forceps, and of the pulling of the severed ureter through both openings made by the forceps. The ureter is secured to the bladder wall by a few interrupted sutures at its lower entrance into the bladder, and the end is permitted to hang free in the cavity of the bladder. The anterior opening is then closed (Figs. 5 and 6).

A technic suggested by Mann of the Mayo Clinic, a report of which has not heretofore been published, has been used in a few of our experiments. Two parallel incisions, one-fourth inch in length and one-half inch apart, are made at right angles to the long axis of the bladder, extending down to the mucosa. This seromuscular bridge is undermined, leaving the mucosa intact. A small stab wound is made through the mucosa at the site of the lower transverse incision. The severed ureter, having been split for one-fourth inch on its anterior surface and armed with No. 00 catgut, is pulled beneath the bridge from above downward and anchored to the inner surface of the wall of the bladder one-half inch below the opening. One or two interrupted sutures are made on each side of the ureter, approximating the transverse incision up to the ureter. No suture is placed into the ureter except the one put through the flap, for the purpose of securing it to the inner side of the wall of the bladder (Figs. 7 and 8).

In making the experimental and clinical observations described in this paper, it has been my purpose to evolve a technic for the reimplantation of the ureter into the bladder, and to study the effect of such operation on the kidney and ureter. Unilateral implantations

---

* From the Mayo Clinic.

* Read before the Section on Genito-Urinary Diseases at the Sixty-Ninth Annual Session of the American Medical Association, Chicago, June, 1918.

* Because of lack of space, this article is abbreviated in The Journal. The complete article will appear in the Transactions of the Section and in the author's reprints.

were performed on eighteen dogs and bilateral implantations on three, giving a total of twenty-four observations.

Coffey's technic was used in eight cases. Observations of the end-results were made from one day to five and one-third months after operation. One animal died from peritonitis on the sixth day. The kidney showed slight hydronephrosis. It was possible to make the ureter leak at the site of anastomosis (Case 1). One death occurred at the end of twenty-four hours. Both ureter and pelvis were dilated, and miliary abscesses were found throughout the kidney. There was also a small localized abscess at the site of the implantation (Case 6). A third animal died from distemper on the tenth day. The pelvis and the ureter both showed a slight hydronephrosis (Case 8). Five animals were examined from three weeks to five and one-third months after operation, and showed an entirely normal kidney and ureter. Two observations on the technic were made:

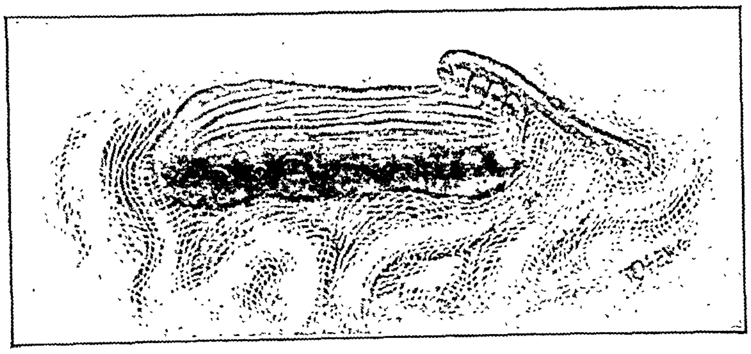

Fig. 2.—Coffey technic completed with bladder everted out of the abdomen.

1. In all instances the ureter was implanted on the posterior wall of the bladder a short distance toward the median line of the original insertion, with the bladder pulled well out of the pelvic cavity. It is convenient and natural to embed the ureter from below upward, but when this is done and the bladder is replaced into the pelvis, an acute angulation in the ureter occurs just at the site of the union with the bladder. If the implantation is reversed, that is, from above downward, the ureter will lie in a line with its entrance through the wall of the bladder. In order to have the open side of the ureter facing into the cavity of the bladder, the splitting of the ureter must be done in its anterior wall (Fig. 9).

2. After some observation the last stay suture, placed about one-fourth inch above the site of implantation, was omitted, as the implantation is performed with the bladder empty and in a state of acute contraction. When this viscus becomes distended a great disproportion occurs between this included section of the ureter and portion of the bladder, and the ureter may be acutely kinked and even pulled out of the wall of the bladder, as occurred in one of the cases (Case 11, Fig. 10).

Stiles' technic was carried out in eight cases, with the modification of splitting the anterior aspect of the wall of the ureter for about one-fourth inch. No suture, except the anchoring suture, was permitted to enter the wall of the ureter. Care was taken to avoid any injury to the proximal end of the severed ureter, and no forceps was placed over the end. A forceps was placed on the side of the bladder and the ureter cut with a thin scalpel about 1 cm. above this clamp. While the sutures infolding the ureter in the wall of the bladder were being tied, a thyroid needle was used as a seeker in order to avoid any undue compression on the anastomosis (Fig. 4). There were six complete successes in this group of eight operations. In one case (Case 11) the ureter pulled out of the bladder. Here the additional stay suture had been used. One animal, sacrificed in a physiologic experiment one and one-third months after operation, showed an advanced pyonephrosis (Experiment 12, Fig. 17).

Five operations were done with the technic devised by Mann. Hydronephrosis resulted in one case four months after the operation. In four cases the kidneys and ureters were normal.

Three implantations were done by the method of Furniss, with normal results. One was a bilateral implantation done at one stage. The placing of a clamp over the proximal end of the ureter was, however, omitted. The small amount of urine leaking from the ureter in such cases will cause no disturbance unless there is previous infection of the kidney, and then a moist pack placed around the ureter will take care of the trouble.

In order to work out the technic, a cystoscopic examination was made under anesthesia in four normal female dogs and in four dogs whose ureters had been implanted. With the animal in the dorsal position, a small speculum was introduced into the vagina and sufficient traction exerted on the labia to bring the urinary meatus into view from its normal location behind the pubic arch. The cystoscope was then quite readily introduced. The ureters were catheterized with No. 4 or No. 5 ureteral catheters in the normal animals. There was obstruction to the catheter in two of the implanted cases; in two others no obstruction occurred.

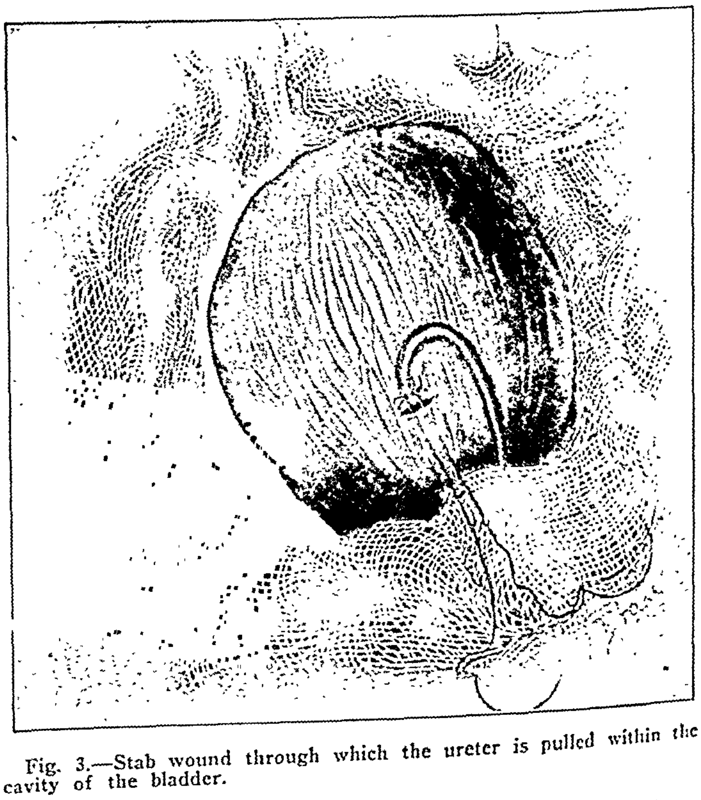

Fig. 3.—Stab wound through which the ureter is pulled within the cavity of the bladder.

In the review of the results of the twenty-four experiments, it was found that there were entirely normal kidneys and ureters in fifteen instances, slight hydronephrosis in two, marked hydronephrosis in one, miliary abscesses of the kidney in one, pyonephrosis in one, normal kidney and hypertrophied ureter in two, and the ureter pulled out in two (Tables 1 and 2). Fifteen implantations (62.5 per cent.) were complete successes. Normally functionating kidneys, including two cases with a slight hydronephrosis, were found in nineteen (80 per cent.). There was complete failure from stenosis, infection and the pulling out of ureters in five cases (20 per cent.).

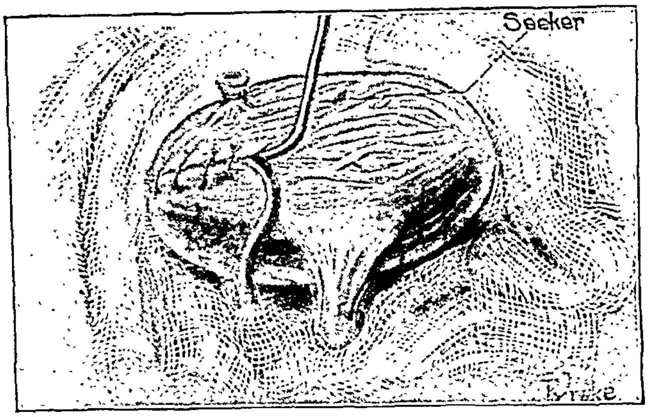

Fig. 4.—Enfolding of the wall of the bladder over the ureter, a seeker being used to avoid compression.

Early in these experiments, fine silk was used for suture material, and in several instances concretions formed around the sutures in the bladder. This did not occur when catgut alone was used.

It is of interest to note that in two cases (Cases 19 and 21) the kidneys were entirely normal, the ureter was hypertrophied and there was no evidence of dilatation. Partial stenosis takes place at the site of the implantation and the muscularis of the ureter undergoes compensatory hypertrophy, consequently dilatation of the pelvis does not occur until this compensation is overbalanced.

TABLE 2.—SUMMARY OF DOG CASES

Number of dogs used in experiment	21
Number of ureters transplanted	24
Coffey's technic	8
Stiles' technic of	8
Mann's technic o	5
Furniss' technic	3
Number of dogs cystoscoped	4
Obstruction to ureteral catheter	2
No obstruction to ureteral catheter	2

Death from	1
Death from distemper	2
Killed in fight	1
Sacrificed in physiologic experiments	6
Nephro-ureterectomy	7
Exploratory operation for result	1
Time elapsing between operation and study of result	1 day to 5⅓ mo.
Normal kidney and ureter	15
Slight hydronephrosis	2
Marked hydronephrosis	1
Pyonephrosis	1
Miliary abscess in kidney	1
Normal kidney and hypertrophy of ureter	2
Normally functionating kidneys including two with slight hydronephrosis (80%)	19
Failure from	1
Failures from	2
Ureter pulled	2
Complete successes (62.5%)	15

Slight dilatation of the pelvis and ureter was found in two cases (Cases 1 and 8), six and ten days respectively after implantation. This was probably owing to edema of the lower end of the ureter and of the wall of the bladder caused by trauma, which subsided in a short time. The utmost care should be taken to minimize trauma during the operation.

In view of the end-results and the simplicity of the operation, the modification of Stiles' technic seems the most suitable in ureterovesical anastomosis. The successful outcome of ureterovesical implantation depends entirely on the technic. This consists of: (1) rigid asepsis to prevent peritonitis and ascending renal infection, (2) a suitable mechanical scheme to establish waterproof anastomosis without causing compression of the ureter, (3) the avoidance of any suture that will enter the wall or lumen of the ureter other than the anchoring suture at its end, and (4) the avoidance of placing any clamp whatever across the extremity of the ureter used in the anastomosis.

CLINICAL REPORT

In twenty-one cases in the Mayo Clinic, the ureter has been implanted into the bladder and the effect on the kidney has been noted. Fifteen patients had extensive resections for tumor of the bladder, and implantation of one ureter; four had ureterovaginal fistula; in one the right ureter opened into the urethra, and in one the left ureter opened into a diverticulum.

TABLE 4.—SUMMARY OF RESULTS OF TRANSPLANTATIONS

Number of cases cystoscoped following transplantation	17
Length of time elapsing between transplantation and cystoscopic examination	18 days to 4½ years
Dilated meatus	9 (54%)
Meatus not seen	4 (23%)
Meatus normal	3 (18%)
Meatus contracted	1 (6%)
Contraction of transplanted meatus	7 (41%)
No obstruction to ureteral catheter	8 (47%)
Obstruction to catheter noted	3 (18%)
Infection of specimen from few pus cells to cloudy urine noted	6 (35%)
Normal function, phenolsulphonephthalein and normal pyelogram	5 (30%)
Small	3 (18%)
Norma	4 (23%)
Functionless kidney	5 (30%)
Dilatation of ureter noted at operation—Cases 10 and 16	2 (12%)
Ureter dissected from dense scar tissue—Cases 5, 12 and 15	3 (18%)

Kidneys showing normal function, 53%; fair function, 18%; functionless, 30%.
Deducting Cases 5, 10, 12, 15 and 16 = normal kidneys, 75%; fair functionating kidneys, 25%.

The patients who were operated on for malignancy and returned for examination have been longest under observation, three for four years and eight for from three months to one year. When implantation was done for conditions other than tumor of the bladder the time elapsing between the operation and the cystoscopic examination varied from eighteen days to four months. The cystoscopic examination consisted of a

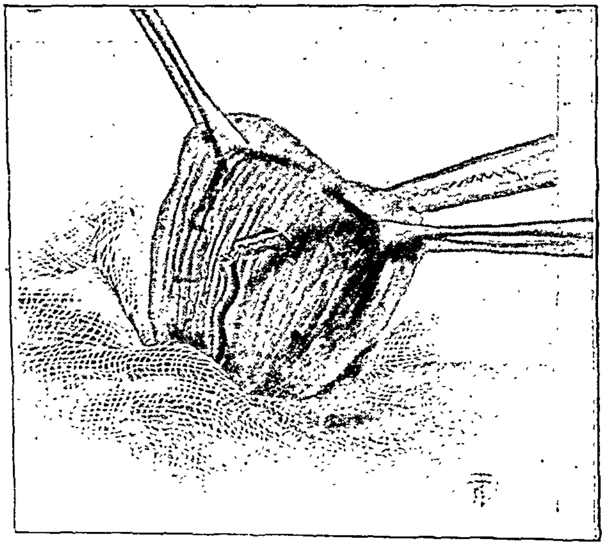

Fig. 5.—The Furniss technic for the implantation of the ureter into the bladder.

careful inspection of the entire bladder. The condition of the implanted meatus as to size and contractions and the appearance of the excretion were noted. Whenever feasible, both ureters were catheterized and a differential functional test with phenolsulphonephthalein was done, followed with a pyelogram of the implanted side. In the cases in which the implanted ureter could not be catheterized, a Garceau catheter was passed well up on the normal side, urine from the bladder was taken from the implanted side and a differential test made. When neither side was catheterized, indigocarmin was given intravenously, and the time of its appearance and the intensity of the color as it appeared at the meatus were noted (Tables 3 and 4).

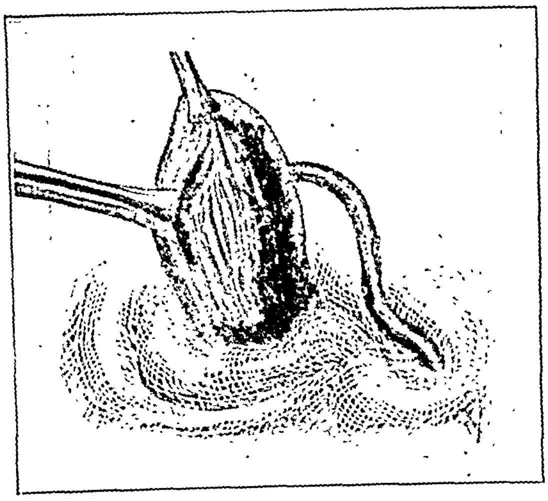

Fig. 6.—The end of the ureter lies free within the cavity of the bladder.

Four patients died following resection of carcinoma of the bladder and implantation of one ureter. At necropsy, the cause of death and the result of the implantation were shown (Table 5).

Seventeen of the twenty-one patients were cystoscoped from eighteen days to four and one-half years after operation. The normal output of phenolsulphonephthalein and a normal pyelogram were obtained in five instances (30 per cent.); the normal phenolsulphonephthalein excretion was obtained in four (23 per cent.), and there was a small hydronephrosis with fair function in three (18 per cent.). Functionless kidneys were found in five instances (30 per cent.). In a review of the histories in the cases of functionless kidneys, two conditions are noted:

1. Marked dilatation of the ureter at the time of the implantation, due to the growth overlying the meatus and causing gradual obstruction in one case (Case 10). In one case (Case 16), in which the right ureter opened into the urethra, there was a dilated ureter.

2. Because of the necessity of resecting a portion of the ureter involved in the malignant growths, where there was very dense scar tissue in ureteral fistulas, the implantation was performed with considerable tension on the ureter (Cases 12 and 15).

In nine cases (53 per cent.) of the seventeen patients, the function of the kidney was entirely normal. There was fair function in three cases (18 per cent.), and functionless kidneys in five cases (30 per cent.). If we deduct those cases in which marked dilatation was noted at the time of operation, and in which the ureters were implanted under tension, normal kidney function occurred in 75 per cent. and fair function in 25 per cent.

Of the four patients who died from the fourth day to the second month after the operation, two showed slight dilatation on the implanted side; in one the pelvis was dilated to three times the normal size, and in one there was no evidence of obstruction.

In view of the fact that functionless kidneys result when the implantations are done with widely dilated ureters, and when it is necessary to put the ureter on tension in order to accomplish the anastomosis, in such cases ligation of the ureter is preferable to implantation.

If, on cystoscopic examination, a tumor of the bladder, which appears malignant, is found overlying one or the other meatus, or in close proximity to it, the opposite ureter should be catheterized to ascertain the functional capacity of the kidney. If, at the time of the operation, a widely dilated ureter is found, or if tension is necessary, the surgeon has definite information regarding the ability of the opposite kidney to carry on the urinary elimination. If, on account of hematuria, spasm of the bladder, spasm or anatomic obstruction, the opposite ureter cannot be catheterized, a combined phenolsulphonephthalein test should be done. If the combined output is normal, or nearly normal, and a widely dilated ureter is found, it is safe to assume that the normal phenolsulphonephthalein output is from the opposite side, and ligation of the ureter may be safely done.

In all cases in which advanced pathologic changes of the kidney and ureter have not occurred prior to surgical relief, and in which tension can be avoided, the reimplantation of the ureter into the bladder should be done.

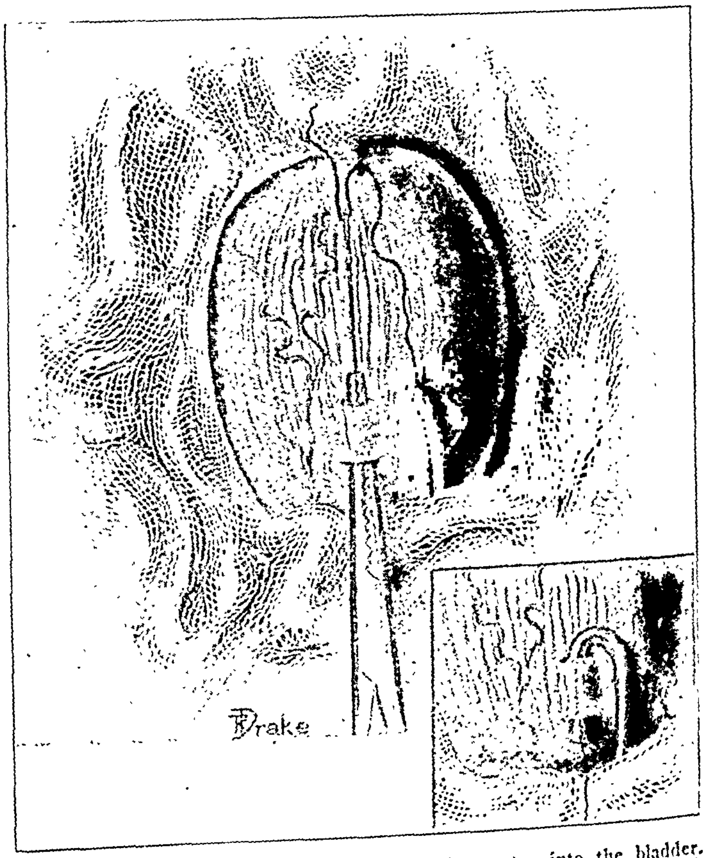

Fig. 7.—Mann's technic for implanting the ureter into the bladder. A seromuscular bridge is undermined and the ureter is pulled beneath this bridge from above downward.

CONCLUSIONS

1. From experimental and clinical observations, it is obvious that a normal or almost normal kidney and ureter should result following the implantation of the ureter into the bladder.

2. The utmost care to minimize the operative trauma must be observed.

3. The placing of a forceps over the end of the uterer should be avoided.

4. No suture should enter the wall or lumen of the uterer other than the anchoring suture placed in the split extremity of the ureter; and the approximation of the wall of the bladder must be accomplished without undue compression.

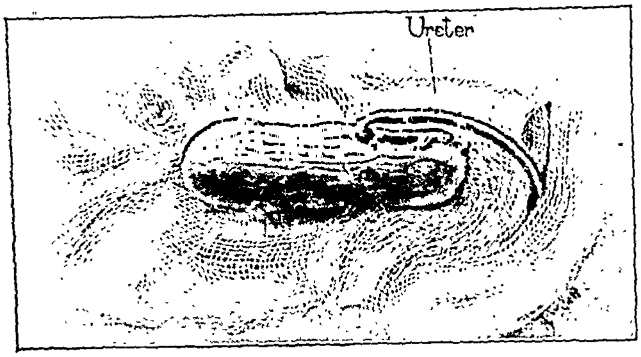

Fig. 8.—Mann's technic of implantation completed, showing the bladder empty and pulled well out of the abdomen.

5. When marked dilatation of the ureter has occurred prior to surgical interference, and when it is necessary to implant the ureter under tension, a successful result is very doubtful and ligation is preferable to any effort of implantation.

REPORT OF CASES

Case 1 (No. 80914).—A woman, aged 40, was admitted to the clinic, March 4, 1913. A diagnosis was made of a broad, flat carcinoma extending over the base of the bladder and into the urethra. Aug. 6, 1913, excision and cautery of the base of the tumor and implantation of the right ureter was done. The patient returned each year for cystoscopic examination. There was no recurrence except a persistent caruncle of the urethra, which was cauterized. Microscopic examination showed it to be inflammatory. Oct. 26, 1917, four and one-fourth years after the resection of the growth, the left ureter was catheterized. The differential functional phenolsulphonephthalein test showed 15 per cent. from the ureter, and 17.5 per cent. from the bladder specimen in fifteen minutes after intravenous injection. Nov. 30, 1917, the right ureter was catheterized easily, and clear urine flowed normally through the catheter. A pyelogram made on this date showed no dilatation of the pelvis (Fig. 23). The patient is in good general condition.

Case 2 (No. 86197).—A woman, aged 50, was admitted to the clinic, June 18, 1913. A diagnosis of malignant papilloma of the base of the bladder was made. June 25, 1913, suprapubic resection of the right quadrant and floor of the bladder with implantation of the right ureter was done. Cystoscopic examination in 1914, 1915, 1916, and 1917 showed no evidence of recurrence. Feb. 8, 1918, four years and seven and one-half months after the removal of the tumor, a dilated right meatus was found. The catheter could not be passed up the ureter. The left ureter was catheterized with a Garceau catheter. The intravenous phenolsulphonephthalein test showed 20 per cent. in the ureter, and 15 per cent. in the bladder in fifteen minutes. The patient's general health is good.

Case 3 (No. 100111).—A man, aged 53, was admitted to the clinic, Feb. 4, 1914. A suprapubic resection of a tumor of the bladder had been done elsewhere, about six months previous to admission. A recurring tumor of the bladder was found, and, Feb. 7, 1914, resection and cautery of one half of the bladder with implantation of the right ureter was done. Nov. 5, 1914, cautery of the bladder for recurrence was again necessary. Cystoscopic examinations in 1915, 1916 and 1917 showed a small recurring growth at the site of the operation scar, which was fulgurated. Examination, December 4, 1917, showed a small reddened area in the old scar but no evidence of recurrence. The right ureter opening was widely dilated, and frequent spurts of urine came from the meatus. The secretion from the right ureter showed a few pus cells. The phenolsulphonephthalein test showed 4 per cent. in the right ureter, and 5 per cent. in the left in fifteen minutes. A pyelogram of the right kidney showed a small hydronephrosis. The patient is now in excellent health (Fig. 24).
